ABSTRACT

Background

The National Radiation Protection Authority (NRPA) of Namibia was tasked in 2005 by the IAEA under the project RAF9/033 to develop diagnostic reference levels for conventional radiographic examinations. To date, no study that examines the radiation dose in diagnostic radiology has been undertaken in Namibia and radiation protection of patients may not be optimised. Diagnostic reference levels acts as a quality assurance tool that identifies procedures or activities where patient doses are high.

Objectives

The purpose of the study was to develop local Diagnostic Reference Levels (LDRL's) for commonly performed conventional radiography projections in Windhoek, Namibia.

The objectives of the study were to:

- Measure KAP (Kerma Area Product) for postero-anterior (PA) and lateral (LAT) chest, antero-posterior (AP) and LAT lumbar spine, AP pelvis, and PA and LAT skull projections.
- Calculate entrance skin and effective doses from the recorded KAP values.
- To compare the KAP, entrance skin doses and effective doses with internationally established reference levels for the same procedure as well as similar studies in Africa.
- Develop conversion coefficients from KAP values for estimation of effective and skin doses in clinical practice.

Method

In this study, three (3) hospitals located in Windhoek, Khomas region were selected and KAP measurements were recorded on 218 patients with a mean weight of 70 ± 5 kg. The entrance skin, and effective doses were calculated through Monto Carlo simulations by entering the geometric data, exposure parameters and equipment specifications and KAP values into PCXMC 2.0 software (Finland). Diagnostic Reference levels (75th percentile), entrance skin doses (ESDs) and effective doses were calculated for anterior (PA) and lateral (LAT) chest, antero-posterior (AP) and LAT lumbar spine, AP pelvis, and PA and LAT skull projections.

Results

The 75th percentiles of the entrance skin doses combined for PA and LAT chest, AP and LAT Lumbar spine, AP Pelvis and PA and LAT skull were, 0.0333 mSv, 0.0663 mSv, 0.1970 mSv, 0.2740 mSv, 0.2497 mSv, 0.0922 mSv, and 0.0584 mSv respectively. The effective doses for the same procedures were 0.0545 mSv, 0.0942, 0.3792, 0.2970 mSv, 0.3061 mSv, 0.0267 and 0.0283 respectively. The highest skin dose was recorded for the lateral lumbar spine projection while the highest effective dose was measured for AP lumbar spine projection.

Conclusion

The ESD's in this study were much lower than previously reported values. However the effective doses were generally similar and compare well with previous studies. On the basis of the results it can be concluded that the effective dose is a better dosimetry quantity than ESD to determine deterministic effects of radiation.

ACKNOWLEDGEMENTS

I wish to thank:

- First and foremost, my Creator and Sustainer for His protection, wisdom and sustainability. For his will shall be done.
- Mrs.F. Davidson (Supervisor) for her professional guidance, direction and, pastoral nature during this research project. Thank you for taking up the challenge and accepting the supervisory role. Your dedication and supervisory skills made this project a success.
- Mr. A. Speelman (Co-supervisor) for his engagement and scientific advice.
- Dr. T. Kotze (Medical Physicist), who took up the challenge to provide statistical advice and partner with us at no extra cost. Your guidance and advice were an inspiration to finish this project.
- Ms. V. Uushona-Mikka for availing the dose area product meter and provision of technical advice regarding the research project. Ms. Uuhona-Mikka is a member of the scientific committee at the National Radiation Protection Authority Namibia.
- The management and entire radiology staff of Katutura Intermediate Hospital, Medical Imaging and Windhoek Central Hospital as well as students who permitted me to conduct this study in their radiology department. A special thanks to Mr. A Maretha and Ms. V Naimas, for assistance with data collection.
- Ms. A. Claasen (Senior Library assistant) for her moral and emotional support as well as providing assistance with locating the necessary literature.
- To my parents, siblings and friends. Your prayers were stronger than mine. Thank you for keeping me grounded, all prayers have been answered according to His Will.
- Last but not least, the financial assistance of the University of Namibia towards this research project is acknowledged. Opinions expressed in this thesis and the conclusions arrived at, are those of the author and, and not necessarily to be attributed to the University of Namibia.

DEDICATION

This thesis is dedicated to my family, through your support and prayers the road travelled was less challenging.

CHAPTER 1

1.1 Background and rationale

Over the past century, ionising radiation has been readily applied in medicine and has now become an indispensable diagnostic tool to evaluate patient's health (UNSCEAR, 2000). Since the discovery of x-rays in 1895, x-ray equipment has undergone various changes with computed and digital imaging systems been introduced and having replaced traditional film-screen systems. It is therefore not surprising that radiation exposure from x-ray examinations has become the largest artificial source of radiation exposure (Sonowane et al., 2010). In the year 2000 it was reported that, medical radiation exposure in developed countries constituted about 50% of global exposure (UNSCEAR, 2000).

The benefits resulting from medical imaging cannot be overstated. However, exposure to ionising radiation has the potential to cause detrimental health effects. These effects are classified as either stochastic or non-stochastic (Kamiya et al., 2015). Stochastic effects are also known as probabilistic, where the incidence, but not severity of appearance, is proportional to the radiation dose received. These effects occur at low doses and are related to the damage to the genetic material at cellular level. Stochastic effects have no threshold dose; examples include heredity diseases (Kamiya et al., 2015). Non stochastic effects are also referred to as deterministic effects and occur once a threshold radiation dose is received. The degree of injury depends on three factors; absorbed dose, dose rate and the quality of radiation. These effects can have either a linear or exponential response to the radiation dose received. Non stochastic effects are further divided into early and late effects. Examples of early effects include haemorrhagic diarrhoea, anaemia, leucopenia, erythema, and epilation. Late effects comprises cataracts, cardiovascular disorders and necrosis (Kamiya et al., 2015).

In a universal effort to protect patients as well as health professionals against the harmful effects of ionizing radiation, the International Atomic Energy Agency (IAEA) published its Basic Safety Standards (BSS) in 1996 (IAEA, 1996). The BSS is based on three cardinal principles, namely, justification, optimisation and dose limitation (IAEA, 1996).

In radiography, justification is the process where radiological requests are evaluated to ascertain the diagnostic efficacy of the procedure based on the clinical history of the patient. (Vom & Williams, 2017). Optimisation of radiation protection comprises the application of different radiographic techniques and imaging parameters in an effort to minimize radiation dose to

patients without compromising image quality. Clinically this implies that radiographers adjust and select imaging parameters with reference to the patient's body habitus while maintaining diagnostic quality (Freitas & Yoshimura, 2009). A quality diagnostic radiograph therefore represents a visual appreciation of the patient's anatomy under examination sufficient to make a clinical diagnosis (Vom & Williams, 2017).

In radiography dose limitation is guided by the As Low As Reasonably Achievable (ALARA) principle. According to the Dosimetry Working Party (DWP) of the Institute of Physical Sciences in Medicine of the College of Radiographers in the United Kingdom (UK), radiographers are responsible for the comfort of patients during radiological procedures (DWP, 1992). As a result, radiographers should be concerned about radiation protection and radiation dose when selecting exposure parameters during radiological procedures. Therefore, radiographers should keep radiation doses as low as reasonably achievable (ALARA) during radiological procedures. It is against this background that diagnostic reference levels were introduced as an indicator for medical exposure (IAEA, 2006), encouraging radiographers to minimise radiation dose and optimise the effects of ionising radiation.

Diagnostic reference levels (DRLs) are defined as "dose levels in medical radiodiagnostic practices for typical examinations for groups of standard-sized patients or standard phantoms for broadly defined types of equipment" (European Commission, 1999:6). DRLs measure radiation doses to patients for a defined set of procedures and act as a quality assurance tool that determines whether or not radiation exposure to patients are optimized. DRLs therefore serve as an indicator of good radiographic practice. If radiation doses delivered to patients are consistently unusually high then there is a need to investigate radiation practices in order to apply corrective measures (Edmonds, 2009; Seeram & Brennan, 2017).

In order to comply with the BSS for medical exposure, authorities that regulate x-ray equipment should determine radiation doses for typical sized adult patients (IAEA, 2006). It is for this reason that the IAEA requested the National Radiation Protection Authority (NRPA) of Namibia in, 2005, to develop diagnostic reference levels for conventional radiographic examinations (Appendix 1). The concept of diagnostic reference levels has now been formally adopted by the Ministry of Health and Social Services (MOHSS) of Namibia and is gazetted in the Atomic Energy and Radiation Protection Act of 2005 (Republic of Namibia, 2005). With the implementation of the Atomic Energy and Radiation Protection Act of 2005, there is a statutory requirement for all radiology departments to establish diagnostic reference levels. It is against this background that the researcher measured the Kerma Area Product (KAP) for conventional

postero-anterior (PA) and lateral (LAT) chest, antero-posterior (AP) and LAT lumbar spine, AP pelvis, and PA and LAT skull x-ray examinations as recommended by the Atomic Energy and Radiation Protection Act, IAEA and ICRP.

1.2 Statement of the problem

The NRPA of Namibia was tasked in 2005 by the IAEA under the project RAF9/033 to develop diagnostic reference levels for conventional radiographic examinations (Appendix 1). To date, no study that examines the radiation dose in diagnostic radiology has been undertaken in Namibia and radiation protection of patients may not be optimised. According to the International Commission on Radiological Protection (ICRP), diagnostic reference levels acts as a quality assurance tool that identifies procedures or activities where patient doses are high (ICRP, 1996). With the implementation of the Atomic Energy and Radiation Protection Act of 2005 (Republic of Namibia, 2005), there is a legal requirement for all radiology departments to establish diagnostic reference levels. Although various international diagnostic reference levels (DRLs) exist, these levels cannot be directly applied to Namibia, as DRLs are context dependent and vary according to the radiographic equipment, technique and exposure factors. Hence, there is a need for country or region specific diagnostic reference levels (ICRP, 1996; Johnston & Brennan, 2000; Seeram & Brennan, 2006). As such, the study measured radiation doses at three (3) different radiology practices in Windhoek for four commonly performed conventional radiographic examinations and established diagnostic reference levels for these procedures. The research was guided by the following research question.

- What are the radiation doses received by patients undergoing conventional x-ray examinations in Windhoek, Namibia?

The purpose of the study was to develop (Local Diagnostic Reference Levels (LDRL's) for commonly performed conventional radiography projections in Windhoek, Namibia.

The objectives of the study were to:

- Measure KAP for postero-anterior (PA) and lateral (LAT) chest, antero-posterior (AP) and LAT lumbar spine, AP pelvis, and PA and LAT skull projections.
- Calculate entrance skin and effective doses from the recorded KAP values.
- To compare the KAP, entrance skin doses and effective doses with internationally established reference levels for the same procedure as well as similar studies in Africa.

- Develop conversion coefficients from KAP values for estimation of effective and skin doses in clinical practice.

1.2.1 Null hypothesis:

DRL's determined for conventional radiography projections used in Windhoek, Namibia are in agreement with international levels.

1.3 Significance of the study

To the best of the researcher's knowledge, no local diagnostic reference dose levels existed in Namibia, and as a result, radiography procedures may not be optimised with regard to radiation dose. Therefore, the local diagnostic reference levels which have been established in this study can be used as baseline data for future studies, until such a time that national diagnostic reference levels are determined.

1.4 Overview of the methodology

The study was conducted in three (3) hospitals located in Windhoek, Namibia. Hospital one (1) was a national referral hospital with a total capacity of 964 beds. Hospital two (2) was a private radiology practice attached to a private hospital with a total capacity of 1024 beds. Hospital three (3) was an intermediate hospital with a capacity of 955 beds. All three hospitals utilise computed or digital radiography x-ray imaging systems and are affiliated to the University of Namibia. Ethical approval was gained from the research ethics committee (REC) of the Cape Peninsula University of Technology as well as the Permanent Secretary of the Ministry of Health and Social Services (Namibia), Director of the National Radiation Protection Authority (NRPA) and permission to conduct the study received from the principal radiographers of the hospitals in the study.

Geometric data, exposure parameters as well as KAP measurements were obtained from 218 patients referred for seven projections that is; PA and LAT chest, AP and LAT lumbar spine, AP Pelvis, PA and LAT skull. Specifications concerning the x-ray equipment for each hospital were obtained from the manufacturer's manual available at each hospital. The information recorded included generator type, name of the manufacturer, type of x-ray tube, anode angle, and total tube filtration.

Entrance skin, and effective doses were calculated through Monto Carlo simulations by entering the geometric data, exposure parameters and equipment specifications and KAP values into PCXMC (2008) 2.0 software (Finland).

Microsoft excel 2016 was used to analyse data. Third (3rd) quartile values for KAP, ESD and ED were calculated. The research question was answered by means of inferential statistical analysis. The correlation between the ESD, ED and KAP were determined using Pearson's tests. The third quartile values of the ESD and KAP obtained were also compared with that published in the literature.

1.5 Delimitations

- Only hospitals affiliated to the University of Namibia, located in Windhoek using computed or digital radiography were included.
- In addition KAP measurements were obtained only on adult patients referred for conventional radiographic projections; PA and LAT chest, AP and LAT lumbar spine, AP pelvis, and PA and LAT skull that had a mean weight of 70kg \pm 5kg.

1.6 Introduction to the structure of the Thesis

In order to understand the radiation doses delivered to patients referred for conventional radiographic projections that is; PA and lateral LAT chest, AP and LAT lumbar spine, AP pelvis; and PA and LAT skull in Windhoek, Namibia, the thesis is structured as follows:

Chapter 2 Literature review

This chapter provides a synopsis for radiation protection as well as the concepts related to radiation dosimetry. This chapter discusses the concept of diagnostic reference levels and dose measurements in radiography. The chapter similarly highlights the factors that affect radiation dose in radiography as well as legislation governing radiation dose measurements.

Chapter 3 Research Methodology

This chapter describes the methodology used in the study. It includes the design, population, sampling as well as ethical principles and procedures for data collection. The measures used to ensure validity and reliability of the research process are also described.

Chapter 4 Research findings

This chapter outlines the research findings from data analysis based on the research question.

Chapter 5 Discussion and conclusion

In this chapter, the results of study are discussed and compared to existing literature. The chapter is concluded with recommendations for future research. It further identifies the limitations experienced during the study.

CHAPTER 2: LITERATURE REVIEW

Ionising radiation plays a vital role in the imaging of the human body. However, it is evident from the literature that radiation has the potential to ionise matter, causing potential harmful effects. In order to protect patients from harmful effects of ionising radiation, radiation dose as a result of medical exposure should be minimised. In order to protect patients against the harmful effects of ionising radiation, the IAEA introduced the three principles of radiation protection, namely justification, optimisation and dose limitation (IAEA, 2006). Diagnostic reference levels (DRLs) are an important quality assurance tool that can be used to minimise radiation doses delivered to patients. Over the past decades, various researchers have investigated radiation doses to patients and have identified the factors that cause dose variation. Factors that affect radiation dose are type of filtration, generator type and the application of manual exposure techniques amongst others (Ng et al., 1998; Johnston & Brennan, 2000; Nyathi et al., 2009; Sonowane, et al., 2010; Abdelhalim, 2011). In this chapter the principles of radiation protection and dosimetry will be discussed. In addition the chapter describes; the legislation regarding DRLs, different methods used to obtain DRLs, comparisons of DRLs in different countries and explains the factors that cause dose variation.

2.1 Principles of radiation protection

2.1.1 Justification

Justification in radiography is the process where radiographers and radiologist evaluate the x-ray request for x-ray examinations by comparing it with the patient's clinical history to determine its validity. In practice justification involves the usage of correct exposure techniques while maintaining diagnostic image quality. Therefore, the principle of justification in radiology means that the risk of exposure to ionizing radiation should be balanced, against the benefits derived from the procedure. A procedure is justified when the benefits of undergoing a procedure outweigh the risk (Von & Williams, 2017).

2.1.2 Optimisation

In radiography optimisation is the process where radiographers minimize the amount of radiation delivered to patients through selection of correct exposure factors (kVp and mAs) (Martin, 2007).

The quality of radiation is dependent on the applied tube potential and the amount of filtration of the x-ray beam. Therefore optimisation of radiation protection comprises the application of different radiographic techniques and imaging parameters in an effort to minimize radiation dose to patients without compromising image quality. Clinically this implies that radiographers adjust and select exposure factors with reference to the patient's body habitus while maintaining diagnostic quality (Freitas & Yoshimura, 2009). A quality diagnostic radiograph therefore represents a visual appreciation of the patient's anatomy under examination sufficient to make a clinical diagnosis (Vom & Williams, 2017).

2.1.3 Dose limitation

Dose limitation applies to occupational exposure of radiation workers and therefore is not applicable to medical radiography procedures (ICRP, 2007). However, the principle of radiation protection in radiography is guided by the As Low As Reasonably Achievable (ALARA) principle. According to the Dosimetry Working Party (DWP) of the Institute of Physical Sciences in Medicine of the College of Radiographers in the United Kingdom (UK), radiographers are responsible for the comfort of patients during radiological procedures (DWP, 1992). As a result, radiographers should be concerned about radiation protection and radiation dose when selecting exposure parameters during radiological procedures. Therefore, radiographers should keep radiation doses as low as reasonably achievable (ALARA) during radiological procedures. Diagnostic reference levels were introduced as quality assurance tool for medical exposure (IAEA, 2006), encouraging radiographers to minimise radiation dose and optimise the effects of ionising radiation.

2.2 Biological effects of radiation

2.2.1 Stochastic effects

Stochastic effects are also known as probabilistic effects, where the incidence, but not severity of appearance, is proportional to the radiation dose received. These effects occur at low doses and are related to the damage to the genetic material at cellular level. Stochastic effects have no threshold dose; examples include heredity diseases (Kamiya et al., 2015).

2.2.2 Non stochastic effects

Non stochastic effects are also referred to as deterministic effects and occur once a threshold radiation dose is received. The degree of injury depends on three factors; absorbed dose, dose rate and the quality of radiation. These effects can have either a linear or exponential response to the radiation dose received. Non stochastic effects are further divided into early and late effects. Examples of early effects include haemorrhagic diarrhoea, anaemia, leucopenia, erythema, epilation. Late effects comprises of cataracts, cardiovascular disorders and necrosis (Kamiya et al., 2015).

2.3 Quantities for patient dosimetry

Various quantities have been documented in the literature that can be used during patient dosimetry studies, namely absorbed dose, entrance skin dose, and entrance surface dose (Heggie, 2008; Kron, 2008; Lee et al., 2013). These quantities play a pivotal role in the assessment of radiation exposure to humans and are of great importance for radiation protection due to the potential harmful effects of ionising radiation (ICRP, 2005).

2.3.1 Absorbed dose (D)

The energy absorbed per unit mass of the patient is known as the absorbed dose and is measured in joule per kilogram (J/kg). This quantity is specific for all types of ionising radiation. The international system (SI) unit for absorbed dose is Gray (Gy). Absorbed dose was previously measured in “rad”, where 100 rad is equal to 1 Gy (Kron, 2008). Mathematically the absorbed dose can be expressed as:

$$D = \frac{d\bar{\epsilon}}{dm}$$

Where, dm is mass of the subject and $d\bar{\epsilon}$ is the average energy absorbed (IAEA, 2007).

2.3.2 Entrance skin dose (ESD)

The entrance skin dose (ESD) also known as entrance surface dose, is defined by (Heggie, 2008) as the absorbed dose in air in the centre of the x-ray beam and the entrance surface of the patient’s skin including backscatter radiation. The ESD is expressed in milligray (mGy). The

ESD is measured by means of thermoluminescent dosimeters placed on the patient skin. Additionally it can be calculated by multiplying the entrance surface air kerma (ESAK) with a backscatter factor (BSF) (Sonowane et al., 2010; European Commission, 1996). Mathematically the entrance skin dose can be expressed as:

$$\text{ESD (mGy)} = \text{ESAK (mGy)} \times \text{BSF}$$

The magnitude of ESD is dependent on the focal skin distance, for example it decreases as the distance from the x-ray source to the skin is increased (Sonowane et al., 2010).

2.3.3 Effective dose (E)

The effective dose is an indicator of harmful effects of exposure to ionising radiation. The effective dose is measured in Sieverts (Sv). It is the product of the tissue weight (W_T) factors of the ICRP, the applicable radiation weighting factor and organ doses (Lee et al., 2013).

2.4 Legislation on diagnostic reference levels (DRL's)

The International Commission on Radiological Protection (ICRP) defines diagnostic reference levels (DRL's) as "a form of investigation level, applied to an easily measured quantity, usually the absorbed dose in air, or tissue-equivalent material at the surface of a simple phantom or a representative patient". Furthermore, the ICRP recommends the establishment of diagnostic reference levels to optimise the radiation dose delivered to patients during radiological procedures (ICRP, 1996).

As previously mentioned, the concept of diagnostic reference levels has now been formally adopted by the Ministry of Health and Social Services (MOHSS) and is gazetted in the Atomic Energy and Radiation Protection Act of 2005 (Republic of Namibia, 2005). With the implementation of the Atomic Energy and Radiation Protection Act of 2005 (Republic of Namibia, 2005), there is now a legal requirement for every radiology department to establish diagnostic reference levels.

The Atomic Energy and Radiation Protection Act of Namibia, sub regulation 38 states that (1) The director general may determine diagnostic reference levels as a condition of registration and ensure that:

- (2) Diagnostic reference levels are used during radiological procedures using radiation as well as during optimisation of radiation protection of patients.
- (3) X-ray equipment is evaluated in order to compare with diagnostic reference levels.
- (4) Radiation doses or activities do not fall significantly below the diagnostic reference levels and if the need arise start an investigation to avoid loss of image quality.
- (5) Corrective actions are initiated when diagnostic reference levels are exceeded to ensure optimisation of radiographic practice.
- (6) Diagnostic reference levels are applied with flexibility and adjusted to allow for higher exposures if necessary, and should be revised as technological and scientific advancements take place (Republic of Namibia, 2005).

A diagnostic reference level can be described as a reference level of dose. The dose descriptor used to establish DRL's is dependent on the radiographic examination and is usually expressed in either entrance skin doses (ESD) or kerma area product (KAP) for conventional radiographic examinations, KAP for fluoroscopic examinations and the dose length product (DLP) for computed radiography (CT) examinations. Dose descriptors selected for DRL's should be an easily measurable quantity of radiation exposure (DWP, 1992; Heggie, 2008; Verdun et al., 2008).

Diagnostic reference values are usually determined by the regulatory authorities in consultation with the various professional bodies and should be established for frequently performed examinations or those that have a high radiation dose (ICRP, 1996). Regardless of the fact that technology has advanced, diagnostic imaging by means of conventional radiography remains the most common method of imaging in Namibia due to its availability and affordability.

Diagnostic reference levels are usually selected by means of the 75th percentile of dose distributions and assist radiographers with the optimisation of radiation protection to patients. This means that 25% of the facilities will surpass the diagnostic reference levels and therefore, the reasons for variation should be investigated (Johnston & Brennan, 2000; Gray et al., 2005).

2.5 Tools used to measure radiation dose

The Dosimetry Working Party (DWP) of the National Radiation Protection Board (NRPB) of the Institute of Physical Sciences in Medicine (IPSM) in the United Kingdom (UK) proposes three methods to measure radiation doses, namely thermoluminescent dosimeters (TLDs) for

measurement of entrance skin doses (ESDs), Kerma area product (KAP) meters for measurement of absorbed dose and the mathematical method using an ionisation chamber and computing absorbed dose from known exposure factors (DWP, 1992). These methods have been well accepted by the International Atomic Energy Agency (IAEA) as well as the European commission and have been applied in various dosimetry studies worldwide. According to Roberts (1995), dosimetry techniques are dependent on the type of examination, whether digital or analogue.

2.5.1 Kerma Area Product (KAP) meter

The KAP is the product of the area of the x-ray beam and the absorbed dose in air at a point in a plane perpendicular to the central axis of the beam also known as the Dose Area Product (DAP) (IAEA, 2007). According to the Dosimetry Working Party (DWP) of the National Radiation Protection Board (NRPB) in the United Kingdom (UK), the KAP is a useful dosimetric quantity that can be used for both conventional and fluoroscopic x-ray examinations (DWP, 1992). KAP can be measured by means of a KAP meter or calculated by means of tube output (Akinlade et al., 2012).

$$\text{KAP (mGycm}^2\text{)} = L(\text{mAs})D_o(\text{mGy/mAs})A(\text{cm}^2)_{(\text{FSD})}$$

Where L is the tube current, D_o is the beam output at 1 meter (m), FSD is the focus to skin distance and $A_{(\text{FSD})}$ is the cross-sectional area of the beam on the patient's skin.

The KAP is a dose descriptor that describes the total amount of radiation used in an examination. It is measured by means of a KAP meter. The KAP meter consist of a radiolucent, flat ionisation chamber with square plates and is used to monitor radiation exposure to patients (Dowsett et al., 2006; Allisay-Roberts & Williams, 2008; Ball et al., 2008). KAP values are usually expressed in Gycm^2 or mGycm^2 and are a good indicator of stochastic effects of radiation. Due to its small size, usually 15 cm^2 , it can be easily be retrofitted on the x-ray tube collimator without any interference with the x-ray procedure (DWP, 1992). According to Ball et al., (2008); and Dowsett et al., (2008) kerma area product measurements are dependent on the radiographic technique employed by the radiographer. Factors that affect the KAP reading are; applied tube potential (KVp), tube current (mA), amount of filtration (mm Al), exposure time (in milliseconds) as well as the area exposed to radiation (cm^2). Hence, the KAP is a good indicator for monitoring the effect of radiographic technique on radiation dose (Ball et al., 2008; & Dowsett

et al., 2008). KAP meters do not measure backscatter radiation due to their attachment on the tube housing; however, they offer instant display of radiation used in an examination and eliminate the need for patient specific dosimeters (Seeram & Brennan, 2006). South African legislation requiring all fluoroscopy x-ray units to be fitted with KAP meters have not been implemented in Namibia (Department of Health South Africa, 2006). For this study, the researcher used a portable KAP meter.

Figure 2.1 KAP meter mounted on the x-ray collimator at one of the research sites.

2.5.2 Thermoluminescent dosimeters

Thermoluminescent dosimeters (TLD's) are widely accepted tools used to measure entrance surface or entrance skin doses during conventional radiography. They are made from dielectric material doped with lithium fluoride (LiF) or lithium borate ($\text{Li}_2\text{B}_4\text{O}_7$) phosphors (Seeram & Brennan, 2006; Hobbie & Roth, 2007). The dosimeters are small in size, approximately 3 mm^2 with a thickness of 0.9 mm, and have an atomic number close to normal body tissue, and therefore, do not appear on radiographs (Abdelhalim, 2011). Usually the dosimeters are attached on the patient's skin in such a manner that it coincides with the centre of the x-ray beam (IAEA, 2006). When the TLD's are exposed to ionising radiation, electrons are trapped and stored in the conduction band of the phosphors (Hobbie & Roth, 2007). Thereafter, the TLD's are placed in a TLD reader and are heated to a temperature of approximately 250°C (Seeram & Brennan, 2006). The trapped electrons of the conduction band overcome the binding energy and fall back to their normal state and gives off light (Hobbie & Roth, 2007). The light is read by means of a photocathode and photomultiplier tube and the signal emitted by the TLD is recorded. The advantage of this method is that it includes backscatter radiation (Seeram & Brennan, 2006). However, the dosimeters require precision and accuracy during handling and needs to be calibrated against predetermined energy levels before dosimetry studies (Abdelhalim, 2011). This makes the process expensive and cumbersome. Another disadvantage

is that the dosimeters have to be read in a laboratory, which may cause variations in the recorded signal due to variation in TLD reader performance (Seeram & Brennan, 2006). In addition, there is no immediate record of the dose received. Furthermore, TLD's are also known for signal fade (Seeram & Brennan, 2006). The dose values obtained with TLD's are expressed in milligray (mGy). Radiation dose measurements by means of TLD's for patient dosimetry during conventional radiography have been a well-established method to measure entrance skin doses during radiological procedures, however, the use of TLD's was not suitable for this research project, as it may cause patient discomfort and irritation, since the dosimeter is placed in direct contact with the patient's skin (Johnston & Brennan, 2000).

2.5.3 Mathematical method using an ionisation chamber

The ionisation chamber was introduced by Behnken in 1924 and is used to measure radiation (Ghom, 2008). It is cylindrical in form and consists of collecting electrodes, negative electrodes, an insulator, an air volume and an outer wall. According to Aird (1988), the chambers contain air at atmospheric pressure. When the ionisation chamber is exposed to ionising radiation, the x-ray photons interact with the air and the walls of the chamber and release secondary electrons. The secondary electrons ionise the air in the chamber. The total charge produced is proportional to the radiation dose imparted on the chamber (Aird, 1988). According to Roberts (1995), this method is used to measure the absorbed dose in air or air kerma at a specific distance from the x-ray source. The Entrance skin dose (ESD) is then computed with reference to the relevant exposure factors.

2.5.4 Monto Carlo Simulations

The Monto Carlo Simulations is a PCXMC (2008) version 2.0 computer programme, developed by the Finish Radiation and Nuclear Safety Authority. A hermaphrodite MIRD5 phantom is used and scaling factors are applied to modify the size of the phantom. Monto Carlo simulations are performed based on the technique factors applied in the clinical setting. The programme calculates effective and organ doses for 29 organs based on ICRP 60 and 103 tissue weighing factors (Sermovaa & Tapiovaara, 1998; Kramer et al., 2008).

The PCXMC (2008) version 2.0 programme simulates how x-ray photons are spread through tissue during exposure. These simulations are based on the interaction of x-ray photons as they pass through tissue. The simulations are completed when all particles are annihilated and drop below a specific threshold level. The organ and effective doses are calculated from the sampling

histories generated and the mean values of the energy deposits. The programme considers the following organs, adrenal glands, brain, breast, colon, gall bladder, heart, kidneys, liver, lungs, lymph nodes, muscle, oesophagus, oral mucosa, ovaries, prostate, pancreas, salivary glands, skeleton, skin, small intestine, spleen, stomach, testicles, thymus, thyroid, urinary bladder, uterus and active bone marrow (Sermovaa & Tapiovaara, 1998; Trap & Johnston, 2008).

2.6 Diagnostic reference levels comparison

As previously mentioned, diagnostic reference levels can be described as a reference level of dose. The dose descriptor used to establish DRL's is dependent on the radiographic examination and is usually expressed in either entrance skin doses (ESDs) or Kerma area product (KAP) for conventional radiographic examinations (DWP, 1992; Heggie, 2008; Verdun et al., 2008).

Table 2.1 shows the entrance skin doses for conventional x-ray examinations. Some report the mean (Aliasgharzadeh et al., 2015), median (Ng et al., 1998; Ofori et al., 2014) and 75th percentile (Osibote & de Azevedo, 2008; Nyati et al., 2009; Sonowane et al., 2010). The table demonstrates ESD's for six countries and shows that values ranged from 0.10 mGy to 0.68 mGy for PA chest. In addition the table also shows that the 75th percentile radiation doses for AP pelvis range from 2.98 mGy to 10mGy. It can be noted from the table that there's a variation in radiation doses, thereby justifying the need of country specific DRLs (ICRP, 1996).

Table 2.1 Comparison of Entrance Skin Doses (ESDs) for the seven projections

Exam	IAEA (1996)	Ng et al., (1998)	Osibote & de Azevedo (2008)	Sonowane et al., (2010)	Nyati et al., (2009)	Ofori et al, (2014)	Aliasgharzadeh et al., (2015)
PA chest (mGy)	0.4	0.3	0.24	0.68	0.10	0.27	0.37
LAT chest (mGy)	1.5	1.2	0.62	1.74	0.22	0.43	0.99
AP lumbar spine (mGy)	10	9.1	2.60	8.39	5.30	3.25	2.18
LAT lumbar spine	30	14.0	4.75	15.66	NR	NR	5.36

(mGy)							
AP Pelvis (mGy)	10	5.3	NR	8.03	2.98	1.31	1.76
PA Skull (mGy)	5	4.7	1.55	6.89	NR	NR	1.39
LAT Skull (mGy)	3	3.0	NR	5.16	NR	NR	1.01
NR- not reported							

Some factors that cause dose variations are applied kilovoltage (kV), type of screens used, type of imaging whether digital or analogue and focus-to-skin distance (Ng et al., 1998; Compagnone et al., 2006; Nyati et al., 2009). For example the setting of manual exposures instead of automatic exposures resulted in dose variations in the study by Nyati et al., (2009), whereas poor collimation practices and short focus film distance resulted in dose variations in the study by Ng et al., (1998). Similar to Ng et al., (1998), a study conducted by Olowookere et al., (2011), found that radiographers fail to adjust the radiographic technique and exposure factors based on the patient's body habitus. Olowookere et al., (2011) found that radiographers used a constant tube potential of 80kVp for patients of different mass and body habitus. In addition, the radiographers used a short focus-to-skin-distance (FSD) for imaging of chest projections. The use of low kVp and constant tube current without adjustment to patient body habitus indicates that patients are exposed to high radiation doses in order to obtain good quality image. This is contrary to the ALARA principle that states that radiographers should obtain radiographs at the lowest possible dose without compromising image quality. Olowookere et al., (2011) concluded that radiographers are unaware of the radiation doses during radiography procedures.

2.7 Dose optimising strategies

The exposure factors selected is directly controlled by the radiographer. These are tube potential energy, tube current, exposure time and quantity of radiation produced.

2.7.1 Tube potential energy (kVp)

The tube potential, also known as the kVp, controls the penetrating ability of the x-ray beam, where high kVp x-ray beams are more penetrating than low kVp beams. When radiographers use low kVp techniques, it results in higher patient doses as some x-ray photons may not have enough energy to penetrate the patient (Seeram & Brennan, 2017). A study on ESD's conducted

by Nyathi, et al., (2009) for chest, pelvis, abdomen, lumbar spine in two x-ray rooms found ESD's to be well within internationally established reference levels. It was also noted that radiographers used a high kV technique for chest radiography (109kV to 125kV for PA chest examinations). This is consistent with international standards.

2.7.2 Tube current (mA)

The tube current controls the quantity of radiation released from the x-ray tube and is directly proportional to the mA. The patient dose is increased by high tube current (mA) (Seeram & Brennan, 2017).

2.7.3 Exposure time.

When exposure times are long the radiation dose to the patient is increased (Seeram & Brennan, 2017)

2.7.4 Radiation quantity (mAs)

The quantity of radiation is equal to the product of exposure time and tube current. When the mAs increases, the radiation dose to the patient increases (Seeram & Brennan, 2017). In a study conducted by Sonowane et al., (2010), dose variations were due to high mA set by radiographers, ranging from 17 to 32 for PA and lateral chest. The mA values were approximately 50% more than the study by Ng et al., (1998). Similar to Ng et al., (1998), a study conducted by Olowookere et al., (2011) indicate that radiographers used a constant tube current of 15 mA and 9 mA for PA chest dependent on patient body habitus. A high mA technique necessitates a lower kVp resulting in higher radiation doses in order to obtain a good quality image.

2.7.5 Collimation

Collimation is the process where radiographers select and restrict the x-ray beam to the area of interest. Collimation therefore determines the field size that will be exposed to radiation. When radiographers apply correct collimation, patient radiation doses may be reduced between 27% to 60% (Fauber & Dempsey, 2013).

2.7.6 Source to image distance (SID)

The minimum recommended SID is usually 100 cm, and is changed based on the anatomical area that need to be imaged (Seeram & Brennan, 2017). The shorter the SID, the higher the dose to the patient and vice versa. When the SID is increased it may significantly reduce the effective doses of up to factor of 23 (Joyce et al., 2013). This finding is consistent with Olowookere et al., (2011), who found that the ESD's may be dependent on the focus-to-skin-distance (FSD). In their study Olowookere et al., (2011) noticed that dose variations was a result of the short FSD (105cm) that was used for PA chest projections instead of the 150-180cm recommended (European Commission, 1996).

2.7.7 Automatic Exposure Control (AEC)

AEC are electronic devices that terminate the radiation exposure once the programmed radiation reaches the image receptor. AEC devices eliminate problems where patients may be overexposed due to different patient body habitus; patient pathology and the wear and tear of the x-ray tube. In order to effectively operate AEC devices, there is a need to train radiographers on how to operate these devices in clinical practice (Seeram & Brennan, 2017).

2.7.8 Equipment type

The type of radiographic equipment whether conventional film-screen, computed radiography or digital radiography will also have an effect on the dose delivered to patients. In a study conducted by Compagnone et al., (2006), computed radiography contributed to higher entrance skin doses when compared to conventional film screen radiography and direct digital radiography. The authors noted that direct digital radiography techniques resulted in lower effective doses up to 43% lower than when film screen radiography were used. Overall, the effective dose calculated for AP and LAT lumbar spine projections was 54% higher when computed radiography systems was used compared to film screen radiography.

2.8 Conversion coefficients

Conversion coefficients are constants that explain the relationship between two dosimetric quantities. Estimation of effective dose by means of the PCXMC programme could be laborious.

Therefore conversion coefficients may be used to estimate entrance skin dose (ESD) or effective dose (E) from KAP values in the radiology department. The conversion coefficients for radiographic procedures can be obtained by dividing the entrance skin dose (ESD) or effective dose (E) by the KAP value and is given E/KAP and skin dose (ESD/KAP) (Hansson & Karambatsakidou, 2000; Compagnone et al., 2005).

The literature review above highlights the importance of diagnostic reference levels in the optimisation of radiation protection to patients. Factors that may cause dose variation and more importantly the need for country specific and region specific diagnostic reference levels were found to be: exposure parameters used such as the tube potential and or mA selected, the radiographic technique selected and source to image distance. In order to minimise the harmful effects of ionising radiation and to keep radiation doses aligned with the ALARA principle it is evident that diagnostic reference levels are an inexpensive tool that can be used to monitor radiation doses to patients. The next chapter will describe the methodology used in the research process.

CHAPTER 3: METHODOLOGY

3. Introduction

The purpose of the study was to develop LDRL's for commonly performed conventional radiography projections in Windhoek, Namibia.

The objectives of the study were to:

- Measure KAP for PA and lateral LAT chest, AP and LAT lumbar spine, AP pelvis, and PA and LAT skull projections.
- Calculate entrance skin and effective doses from the recorded KAP values.
- To compare the KAP, entrance skin doses and effective doses with internationally established reference levels for the same procedure as well as similar studies in Africa.
- Develop conversion coefficients from KAP values for estimation of effective and skin doses in clinical practice.

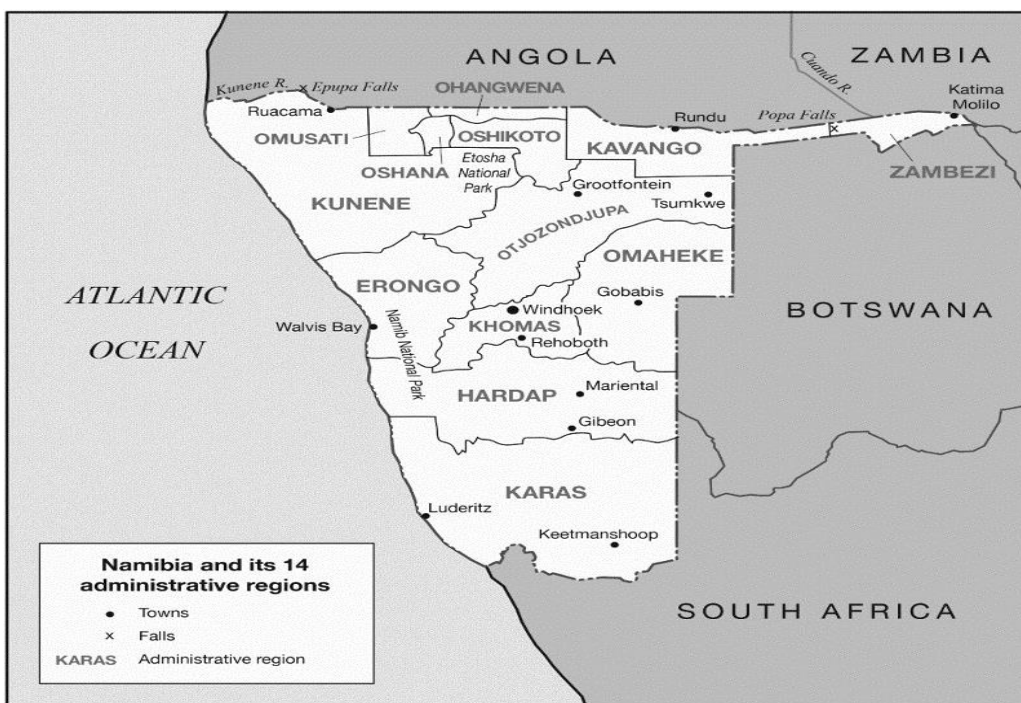

This chapter describes the research design, sampling strategies, scope, research instrument and procedures that were followed to collect data as well as ethical considerations applied during the study.

3.1 Research design

A prospective, quantitative research design was adopted to measure the KAP values, and calculate ESD, ED and develop conversion factors for four conventional radiographic examinations. The study was divided into two phases. Phase one involved a quantitative approach where KAP measurements were obtained and phase two was a correlational approach to calculate ESD and ED using the PCXMC (2008) 2.0 Monte Carlo Software.

3.1.1 Site Selection:

The sampling frame for selecting the research sites was the geographical location of Windhoek Namibia (Figure 3.1).

Source: (Hitchcock, 2015)

Figure 3.1 Map of Namibia illustrating, the research site

Two public and one private hospital located in Windhoek registered with the National Radiation Protection Authority were approached to participate in the study through a letter of invitation (refer to appendix 2 to 4). The letter of invitation explained the purpose and motivation of the study. Windhoek is located in the Khomas region of Namibia and consists of one (1) national referral hospital, one (1) Intermediate hospital, and one (1) health centre that provide radiological services to patients. In addition, there are approximately seven private radiology facilities that also provide x-ray services to patients. The three hospitals in Windhoek were selected because they employ computed radiography and digital radiography in their radiology departments whereas the other regions still employ analogue systems. In addition, they are the three training hospitals affiliated to the University of Namibia, and are the largest hospitals in Namibia. The researcher is employed as an assistant lecturer at the University of Namibia and could therefore gain access to the selected research sites.

These hospitals were purposefully selected in the geographical area of Windhoek as they are representative of radiography practices in the area thus increasing the reliability and validity of the results for radiation dosimetry studies (Hart et al., 2000).

3.1.2 Equipment selection

From each hospital, the x-ray room dedicated for conventional radiographic examinations was identified using a purposeful sampling method. Information regarding the x-ray equipment was recorded. This included; type of generator, type of x-ray tube, filtration, waveform, presence of an anti scatter grid and the ratio, focal spot size, automatic exposure control (AEC), and presence of quality assurance programmes. Refer to (appendix 5) for a copy of the data collection sheet (DWP, 1992; Council of European Commission, 1996; Johnston & Brennan, 2000; Abdelhalim, 2009). Specifications regarding the x-ray equipment are given in table 3.1 below.

Table 3.1 Specifications regarding x-ray equipment at different study sites

Hospital	1	2	3
Type of x-ray unit	Computed (CR)	Direct Digital (DR)	Direct Digital (DR)
Manufacturer	Philips	Siemens	Philips
X-ray tube	Ceiling-suspended	Ceiling-suspended	Floor mounted
Generator	Optimus 50kW	HV 50kW generator	M cabinet CXA Pro 50kW
Total filtration	≥2.5mm Al at 100 kV	≥2.5mm Al at 80 kV	≥2.5mm Al at 100 kV
Inherent filtration	≤0.30mm Al	≤0.60 mm Al	≤0.30mm Al
Motorized filters	2mm Al 1mm Al + 0.1 Cu 1mm Al + 0.2 Cu	2mm Al 1mm Al + 0.1 Cu 1mm Al + 0.2 Cu	2mm Al 1mm Al + 0.1 Cu 1mm Al + 0.2 Cu
Anode angle	13°	12°	13°

Information regarding the anode angle was collected retrospectively as this was not included during the initial phase of the data collection process. This information was used as input data for Monto Carlo Simulations in phase two of the research project.

- The x-ray unit at hospital 1 was a Philips Duradiagnost. It consisted of a 50kW Optimus generator, with a ceiling suspension (Figures 3.2 and 3.3).
- The x-ray unit at hospital 2 was a Siemens Multix Fution Max RF 80. It consisted of 50kW generator with ceiling suspension (Figures 3.4 and 3.5).

- The x-ray unit at hospital 3 was a Philips Duradiagnost 4. It was a floor mounted x-ray tube with a CXA Pro 50kW generator (Figures 3.6 and 3.7).

Figure 3.2 Philips Duradiagnost at research site 1

Figure 3.6 Philips Duradiagnost 4 at research site 3

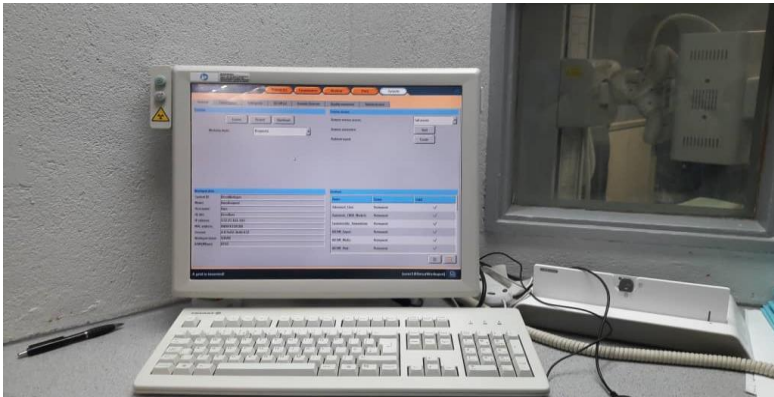

Figure 3.7 Philips Duradiagnost 4 controls and display at research site 3

KAP values were obtained from a portable KAP meter (VACUDAP, Germany) (Figure 2.1) that was retrofitted onto the collimator of each of the x-ray machines. The KAP values was obtained by the research assistant and recorded on the research instrument (refer to appendix 6). The KAP meter was reset after each exposure. The KAP meter was calibrated prior to commencement of the study (see appendix 7). There was only one KAP meter available to the

researcher, therefore data could not be collected concurrently. It was initially anticipated that KAP values be obtained on a sample of 20 patients for each examination at each hospital. However, for some examinations a minimum of 10 patients were recruited. This was consistent with international guidelines which recommend that 10 patients be included for each examination (DWP, 1992; European Commission, 1996; IAEA, 2007).

3.1.3 Study population

The population was all adult patients that underwent chest PA and LAT, lumbar spine AP and LAT, pelvis AP, and skull PA and LAT at the different study sites from June 2014 to July 2017.

3.1.4 Sampling of conventional radiography procedures

A purposive sampling method was used to select research participants. Chest examinations were included because they are most commonly performed procedure, whilst lumbar spine examinations have a high radiation dose and low diagnostic yield (Khoo et al., 2003; IAEA, 2009). The ICRP recommends that diagnostic reference levels be established on the most frequently performed examinations or examinations with high radiation doses (ICRP, 1996). However, the IAEA request in 2005 suggested the establishment of diagnostic reference levels for common radiographic examinations. Extremity radiographs have not been considered, as the exposure factors employed during these procedures are usually relatively low. According to (Ofori et al., 2012), it is important to include pelvic radiographs in patient dosimetry studies. The pelvis contains both male and female sex organs, which are highly sensitive to ionising radiation and should always be protected during radiography examinations hence it was included as part of establishing DRLs for this study.

3.1.5 Inclusion criteria

It is known that the patient's weight may affect radiation dose results. Therefore only adults that underwent chest, lumbar spine, skull and pelvis x-ray examinations aged ≥ 18 years and that weighed ≥ 65 kg and ≤ 75 kg were included in this study. Guidelines provided by the dosimetry working party, European commission, and IAEA states that patients must weigh more than 60 kg but less than 80 kg (DWP, 1992; European Commission, 1996; IAEA, 2007). The weight restriction in this study ensured that the mean weight of patients were in the range of 65-75kg which is indicative of an average patient of 70kg (Hart et al., 2000). The study followed

guidelines on direct dose measurements as established by the dosimetry working party (1992) of the National Radiological Protection Board (NRPB) of the College of Radiographers in the United Kingdom, European commission (1996) and International Atomic Energy Agency (IAEA, 2007). The NRPB recommends that dose measurement studies be performed on a minimum of 10 patients, rather than phantoms or free air in order to provide a true measurement of clinical practice. In order to meet the objectives, KAP measurements were obtained from 218 participants undergoing conventional radiography examinations.

3.1.6 Exclusion criteria

All patients that were younger than 18 years and whose weight was outside the recommended range of 65kg to 75 kg were excluded. Similarly all vulnerable population such as mentally, physically challenged, imprisoned patients or critically ill patients were excluded from the study.

3.1.7 Data collection procedure

Data was collected by the researcher and a trained research assistant at each research site. The research assistants were all qualified diagnostic radiographers. Data was collected on 218 patients and 7 projections (379 examinations). A total of 61 participants were recruited for chest examinations (mean weight =69.86 kg), 48 for lumbar spine examinations (mean weight = 69.51kg), 57 for pelvis examinations (mean weight =70.59 kg) and 52 for skull examinations (mean weight =69.77 kg) refer to Table 3.2 below.

Table 3.2 Summary of the sample size and exposure parameters used at the different study sites

Examination	PA Chest	LAT Chest	AP Lumbar Spine	LAT Lumbar Spine	AP Pelvis	PA Skull	LAT Skull
Hospital 1	CR unit						
No of patients	20	20	20	20	26	21	21

*ranges are shown in parenthesis ()							

The researcher and trained research assistant recorded the participants weight, height, x-ray number, anatomical thickness of part under investigation, age, gender, hospital, applied kilovoltage (kV), exposure time, source to image distance (SID), tube current (mA or mAs), automatic exposure control (AEC) settings if applied as well as KAP meter values for each

radiographic examination. [Refer to appendix 6. (European Commission, 1996; Johnston and Brennan, 2000; IAEA, 2004)].

The participants' weights were measured inside the x-ray room, with a digital bathroom scale. Height measurements were obtained by means of a measuring tape that was attached on the wall. The patient thickness (PT) in the centre of the x-ray beam was measured by means of a measuring tape running from the x-ray tube to the table top. Once the distance from the x-ray source to the table top has been measured, the thickness of the anatomical part was measured by measuring the distance from the x-ray source to the patient (STP) where the beam is centred. Therefore, patient thickness was calculated for each projection by subtracting the source to patient distance from the source to table top distance.

In order to determine patient thickness: the source to patient thickness was measured as follows:

PA Chest projection: distance from the x-ray source to the surface of the patient in the midline at the level of the 7th thoracic vertebra where the radiographer centres the x-ray beam (Bontrager & Lampignano, 2013).

LAT Chest projection: distance from the x-ray source to the surface of the patient in the midaxillary region at the level of the 7th thoracic vertebra where the radiographer centres the beam (Bontrager & Lampignano, 2013).

AP Pelvis: distance from the x-ray source to the surface of the patient in the midline 5 cm below the level of the Anterior Superior Iliac Spine (ASIS) where the radiographer centres the beam (Bontrager & Lampignano, 2013).

AP Lumbar spine: distance from the x-ray source to the surface of the patient in the midline at the level of the iliac crest where the radiographer centres the beam (Bontrager & Lampignano, 2013).

LAT Lumbar spine: distance from the x-ray source to surface of the patient at the level of the iliac crest where the radiographer centres the beam (Bontrager & Lampignano, 2013).

PA skull: distance from the x-ray source to the surface of the patient, in the midline midway between the External Auditory Meatuses to exit at the Glabella (Bontrager & Lampignano, 2013).

LAT skull: distance from the x-ray source to the surface of the patients' skin at a point midway between the Glabella and inion where the radiographer centres the beam (Bontrager & Lampignano, 2013).

3.2 Research assumptions

The research was based on the following assumptions:

- KAP values were consistently and accurately recorded.
- The research assistant and researcher adhered to the data collection procedure when recruiting research participants.
- All equipment was properly calibrated and working properly.
- The x-ray equipment underwent the mandatory periodic quality assurance checks.

3.3 Dose calculations

During the second phase a correlational approach was adopted to calculate the effective and entrance skin doses from the KAP measurements using PCXMC 2.0 software programme. The Monto Carlo programme was developed in 1997. It calculates organ and effective doses based on the ICRP (60) and ICRP (103) using the different tissue weighting factors of patients. The physical parameters for patients (height, weight, as well as the exposure data (focal to skin distance (FSD), x-ray field size, filtration material and anode angle, projection (AP, PA or LAT), KAP value, kilovoltage (kVp), source to detector distance (SID) was entered into the Monto Carlo PCXMC 2.0 (Finland, 2008) software programme (Bor, et al, 2004). Refer to appendix (8-28)

The PCXMC (2008) 2.0 programme simulates how x-ray photons are spread through tissue. The simulation is based on different attenuations and interactions that the photons experience as they pass through the different body tissues (Sermomaa & Topiovaara, 1998). In this study simulations were performed with 20000 histories for each radiographic projection using the exposure factors for each patient. A study conducted by (Behardien Peters, 2017) shows that using more interactions only slows the computer while the effective and skin doses may not differ significantly (1%). The energy deposited was used to calculate effective and entrance skin doses for each projection. The x-ray field size for some projections was not recorded. It was assumed that the collimated field size was spread over the maximum area of the image receptor (refer to table 3.3).

Table 3.3 Estimated field size of image receptors for the different x-ray examinations

Examination	Field size (cm x cm)
Chest (PA)	35 x 43
Chest (LAT)	35 x 43
Lumbar Spine (AP)	35 x 43
Lumbar Spine (LAT)	35 x 43
Pelvis (AP)	35 x 43
Skull (PA)	24 x 30
Skull (LAT)	24 x 30

Additional parameters entered into the Monto Carlo programme is shown in the table 3.4 below.

Table 3.4 Parameters selected for the Monto Carlo programme for the different radiographic projections.

Parameters	Chest (PA)	Chest (LAT)	Lumbar Spine (AP)	Lumbar Spine (LAT)	Pelvis (AP)	Skull (PA)	Skull (LAT)
X ref and Y ref	0	0	0	0	0	0	0

Filtration	2.5mm Al	2.5mm Al	2.5mm Al	2.5mm Al	2.5mm Al	2.5mm Al	2.5mm Al

3.4 Delimitation of the research

- Only hospitals affiliated to the University of Namibia, located in Windhoek using computed or digital radiography were included.

- In addition KAP measurements were obtained only on adult patients referred for conventional radiographic projections; PA and LAT chest, AP and LAT lumbar spine, AP pelvis, and PA and LAT skull that had a mean weight of 70kg \pm 5kg.

3.5 Reliability and validity of the research instrument

Reliability of a research instrument can be described as the extent to which the research instruments yields the same results over time. In other words, the ability to consistently and accurately reproduce the data needed for analysis (Schneider et al., 2003). For the purpose of this research, digital bathroom scales were used to obtain patients' weights. This eliminated inter-reader variability when obtaining patients' weights. Similarly measuring tapes attached to the x-ray tube marked in millimetres (mm) were used to measure participants' thickness, as well as the participants' height. These measurements were verified by the radiographer positioning the patient. The KAP meter (VACUDAP, Germany) was calibrated at the manufacturer (refer to appendix 7). It is recommended that KAP meters be calibrated annually. A medical physicist employed at the National Radiation Protection services of Namibia was consulted to calibrate the KAP meter upon installation at each research site. In order to ensure that data were collected in a consistent manner, the researcher provided training to the research assistants regarding the research protocol.

3.6 Sources of uncertainty

The KAP meter was calibrated against a reference instrument IEC 60580 and has a combined uncertainty of $\pm 25\%$. Therefore the KAP meter might overestimate the KAP values (refer to appendix 29). The KAP meter values were corrected using the correction factor for kilovoltage ≥ 70 kVp (refer to appendices 30 and 31). The digital scale was calibrated by placing it on a flat surface; it was reset to zero before weight measurement were obtained, only patients whose weight has been obtained by the researcher or research assistant was included in the study.

3.7 Pilot study

Uys and Basson (1985) describe piloting as a small study that helps the researcher to refine the data collection plans with reference to the data collection procedure and equipment. In addition, it helps with conceptual clarification of the research design as well. A pilot study was conducted on five patients at one of the selected hospitals using the methodology described in the research

proposal. This allowed for adjustments in the data collection sheet and allowed the researcher to accustom himself with the research instruments and research participants (Uys & Basson, 1985). The data obtained during the piloting of the instrument was not included in the final data analysis.

3.8 Research Ethics

Ethical approval was sought from the Health and Wellness Research Ethics committee of the Cape Peninsula University of Technology (appendices 32-34). Permission to conduct the study was granted by the; Permanent Secretary of the Ministry of Health and Social Services (MOHSS) in Namibia (appendix 35), the Director of the Radiation Protection Services (appendix 36), as well as the principal radiographers and practice managers at the research sites (refer to appendix 37).

The ethical principles of non-maleficence, beneficence, justice and respects for autonomy were followed throughout the research process (Pera & van Tonder, 2011). The objectives of the research were explained to participants upon arrival at the x-ray department. The risk of the study was negligible, as it only recorded the patient's weight, height and anatomical thickness as well as the kerma area product values of patients referred for the selected examinations without changing the protocol or positioning technique and did not interfere with the management or diagnosis of the patient. Patients were also not exposed to any additional radiation during the research process. In order to respect the patient's right to privacy, all measurements were obtained inside the x-ray room. Patients were included in the study on a voluntary basis after careful explanation of the research objectives and after informed consent had been obtained. Consent letters was in English and a translator was used in cases where the participant could not converse in English. The patient information leaflet and consent form is found in appendix 38. The translator was a qualified radiographer or student as not to breach patient confidentiality. The data obtained was stored and locked in the researcher's office, where only the researcher had access. The data collection form was also coded in order to protect the identity of research participants and to maintain anonymity. The data recorded from the patient was limited to the patients' weight, height, and anatomical thickness, age, gender and exposure factors and x-ray number (refer to appendix 6). No names or hospital number was required for this study. The hospitals were each assigned a study code so that the identity of participants were not be revealed during publication of the results.

3.9 Data analysis

The raw data obtained in this study was entered into a computer using Microsoft Excel 2016, and was analysed by using descriptive and inferential statistics (Marshall & Jonker, 2010). The data analysed included the patient's height, weight, equipment as well as exposure parameters. The researcher used the 3rd quartile of KAP meter values to set DRL's for the four conventional x-ray examinations (7 projections) (DWP, 1992). Six statistical tests were used during data analysis, correlation, regression analysis, linear correlation co-efficient, Co-efficient of determination (R^2), Chauvenet's criterion test as well as Pearson's co-efficient of skewness. In this study a regression line was drawn to correlate entrance skin doses with KAP values for each radiographic examination.

3.9.1 Linear regression

In this study linear regression was used to assess the relationship between the KAP values and the calculated skin dose for the four conventional (7 projections) examinations. A straight (regression) line was drawn to join all data points on the scatter plots. The regression line was used to quantify the relationship between the KAP and ESD's. When there is a linear relationship between two variables, the linear regression model is applied to predict the effect on the independent variable on dependant variable (De Muth, 2006).

3.9.2 Correlation

This is a statistical technique that determines the relationship between two variables (Machin et al., 2007). The strength and direction of the relationship is denoted by the correlation coefficient abbreviated r . The correlation coefficient ranges from -1 to +1, and demonstrate the relationship between variables. A positive relationship is demonstrated by a linear correlation where negative relationship is depicted by an inverse proportional correlation. Therefore when one value increases the other value decreases (Machin et al., 2007). A linear relationship is therefore between ($-1 \leq r \leq +1$).

3.9.3 Co-efficient of determination, R^2

The co-efficient of determination, R^2 , is a statistical measure that is used to evaluate the relationship between the independent and dependant variable. R^2 is applied to explain how one

variable influences the other and ranges from ($0 \leq R^2 \leq 1$). In addition R^2 illustrates the strength of the relationship between the independent and dependant variable. On a scatter plot diagram, R^2 is used to determine how data is scattered around the mean of y values. R^2 , is therefore described as the ratio of explained variation to the total variation expressed as percentage. R^2 describes data adjacent to the regression line. For example if $r=0.91$, then $R^2=0.8281$. This suggests that 82.81% of the difference in y values can be explained by the linear relationship between x and y whereas the residual 17.79% remains unexplained (De Muth, 2006; Mckillup, 2006; Mathbits, 2019).

3.9.4 Chauvenet's criterion test

The Chauvenet's criterion test is a test used in the rejection of outliers (Harris & Taylor, 2006; Lin & Sherman, 2007; Reddy, 2011). Knowledge of the standard deviation and mean of the sample under investigation is required. It is used to reject a data point for small data sets up to a 1000, and is applied to samples that are either normally distributed, skew or multi-modal (Harris & Taylor, 2006; Lin & Sherman, 2007; Reddy, 2011).

The formula for data rejection were

$$\frac{d_{max}}{S_x} = 0.819 + 0.544 \cdot \ln(n) - 0.02346 \cdot \ln(n^2)$$

Where, S_x , is the standard deviation of the data set and n is the number of data points. Data can be rejected by comparing a specific data point to the mean of the data by using a normal probability table (Harris & Taylor, 2006; Lin & Sherman, 2007; Reddy, 2011).

The KAP values for each of the projections that were very different from the means were investigated to see if they influenced the results. The data points were retained as they did not have a significant effect on the results.

3.9.5 Pearson's Co-efficient of skewness

The Pearson's co-efficient of skewness was used to determine how data was distributed around the mean.

$$\text{Co-efficient of skewness} = \frac{3(\text{Mean} - \text{Median})}{\sigma}$$

The coefficient of skewness ranges from -3 to 3 and indicates whether data is positively or negatively skewed. When data is positively skewed the mean is greater than the median, whereas negatively skewed data is presented when the mean is smaller than the median. If the data is greatly skewed, one has to be cautious when removing outliers (Arulmozhi & Muthulakshmi, 2009; Statistics How To, 2019).

3.10 Summary of Chapter

This chapter described the methodology used to measure KAP for PA and lateral LAT chest, AP and LAT lumbar spine, AP pelvis, and PA and LAT skull projections. The chapter also highlights the statistical measures employed to execute the research study. In the following chapter the results of the study will be presented.

CHAPTER 4: RESULTS

The research study measured KAP for PA and lateral LAT chest, AP and LAT lumbar spine, AP pelvis, and PA and LAT skull projections. The 75th percentile of KAP values were used to establish local DRLs for the seven projections using a protocol established by the dosimetry working party (1992), which recommends that radiation dose measurements be obtained on a minimum of 10 patient whose weight lies between 65 and 75 kg. This method ensured that the mean weight of the study sample was between (65kg-75kg) which is considered the average weight of an adult (70 kg).

The relationship between the recorded KAP values and the patient's estimated skin dose was assessed using regression analysis, correlation coefficient, R as well as coefficient of determination, R².

This chapter presents the mean, median and 75th percentile KAP values of entrance skin doses and effective doses recorded for PA and, AP and LAT lumbar spine, AP pelvis AP, PA and LAT skull at the three study sites.

4.1 Chest projections

Table 4.1 shows the mean, median and 75th percentile KAP values, skin and effective doses for the PA and lateral chest projections at each hospital separately and then the combined values for PA and lateral chest projections (refer to appendices 8-13). The 75th KAP value for PA chest projections was 38.2 cGy.cm², 10.4 cGy.cm², and 7.6 cGy.cm² at hospitals 1, 2 and 3 respectively (appendices 8-13). The combined 75th percentile of KAP was 26.3 cGy.cm². The median effective dose calculated by the PCXMC 2.0 programme was 0.0687 mSv, 0.0208 mSv, and 0.0169 mSv respectively, with a combined effective dose of 0.0220 mSv. The 75th percentile KAP value for hospital 1 was considerably higher than the combined KAP value, while the KAP values for hospital 2 and 3 were considerably lower.

For the LAT chest projections, the 75th KAP value was 51.6 cGy.cm², 52.9 cGy.cm², and 26.7 cGy.cm² at hospitals 1, 2 and 3 respectively. The combined 75th percentile of KAP was 47.0 cGy.cm². The median effective dose calculated by the PCXMC 2.0 programme was 0.0793 mSv, 0.0855 mSv, and 0.0474 mSv respectively, with a combined effective dose of 0.0687 mSv. The 75th percentile KAP value for hospital 1 and 2 was considerably higher than the combined KAP value, while the KAP values for hospital 2 and 3 were considerably lower.

A regression line was drawn to correlate skin dose with KAP. There was a linear correlation for both PA (R=0.9936) and LAT (R=0.9295) chest projections combined (refer to table 4.1 and figure 4.1 and 4.2). Similarly a linear correlation was observed for both PA and LAT chest at hospitals 1, 2 and 3 respectively (refer to appendices 8-13, and 39-44).

Table 4.1: KAP, skin and effective doses for Chest projections

Radiographic projection	Hospital 1		Hospital 2		Hospital 3		Combined	
	PA	LAT	PA	LAT	PA	LAT	PA	LAT
Mean KAP (cGy.cm ²)	34.3	44.9	9.4	44.3	7.2	22.5	17.0	37.4

Effective dose (mSv) 75 th percentile	0.0759	0.1056	0.0229	0.1086	0.0202	0.0616	0.0545	0.0942

*Median values

Values are for linear fit unless otherwise stated.

Figure 4.1 Linear fit for PA chest projections comparing skin dose and KAP values at the three research sites.

Figure 4.2 Linear fit for LAT chest projections comparing skin dose and KAP values at the three research sites.

4.2 Lumbar spine projections

Table 4.2 shows the mean, median and 75th percentile KAP values, skin and effective doses for the AP and lateral lumbar spine projections at each hospital separately and then the combined values for AP and lateral lumbar spine projections (refer to appendices 14 -19).

The 75th KAP value for AP lumbar spine projections was 129.7 cGy.cm², 307.1 cGy.cm², and 124.6 cGy.cm² at hospitals 1, 2 and 3 respectively (refer to appendices 14 – 19). The combined 75th percentile of KAP was 175.2 cGy.cm². The median effective dose calculated by the PCXMC 2.0 programme was 0.2017 mSv, 0.3771 mSv, and 0.1176 mSv respectively, with a combined

effective dose of 0.2248 mSv. The 75th percentile KAP value for hospital 2 was considerably higher than the combined KAP value, while the KAP values for hospital 1 and 3 were considerably lower.

For the LAT lumbar projections, the 75th KAP value was 231.7 cGy.cm², 279.7 cGy.cm², and 130.0 cGy.cm² at hospitals 1, 2 and 3 respectively. The combined 75th percentile of KAP was 235.5 cGy.cm². The median effective dose calculated by the PCXMC 2.0 programme was 0.1593 mSv, 0.3273 mSv, and 0.1245 mSv respectively, with a combined effective dose of 0.1864 mSv. The 75th percentile KAP value for hospital 2 was considerably higher than the combined KAP value, while the KAP values for hospital 1 and 3 were considerably lower.

A regression line was drawn to correlate skin dose with KAP. There was a linear correlation for both AP (R=0.9938) and LAT (R=0.7085) lumbar spine projections combined (refer to table 4.2 and figure 4.3 and 4.4). Similarly, a linear correlation was observed for both AP and LAT Lumbar spine projections at hospitals 1, 2 and 3 respectively (refer to appendices 14-19, and 45-50).

Table 4.2: KAP, skin and effective doses for Lumbar spine projections

Radiographic projection	Hospital 1		Hospital 2		Hospital 3		Combined	
	AP	LAT	AP	LAT	AP	LAT	AP	LAT
Mean KAP (cGy.cm ²)	117.3	192.0	240.4	250.1	90.5	94.6	154.7	190.2
Median KAP (cGy.cm ²)	93.1	181.6	175.6	234.1	68.8	80.1	124.9	182.6
DRL (75 th percentile)	129.7	231.7	307.1	279.7	124.6	130.0	175.2	235.5

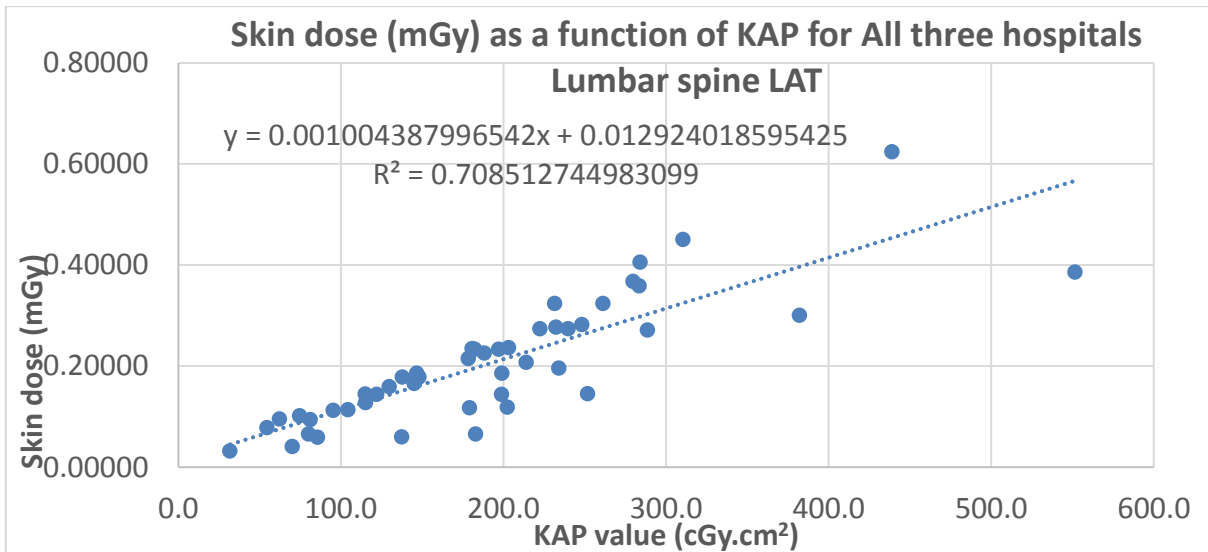

Figure 4.4 Linear fit for LAT Lumbar spine projections comparing skin dose and KAP values at the three research sites.

4.3 Pelvis projections

Table 4.3 shows the mean, median and 75th percentile KAP values, skin and effective doses for the AP pelvis projections at each hospital separately and then the combined values for AP pelvis projections (refer to appendices 20-22).

The 75th KAP value for AP pelvis projections was 194.9 cGy.cm², 328.8 cGy.cm², and 137.7 cGy.cm² at hospitals 1, 2 and 3 respectively (refer to appendices 20-22). The combined 75th percentile of KAP was 209.5 cGy.cm². The median effective dose calculated by the PCXMC 2.0

programme was 0.2220 mSv, 0.3386 mSv, and 0.1562 mSv respectively, with a combined effective dose of 0.2186 mSv. The 75th percentile KAP value for hospital 2 was considerably higher than the combined KAP value, while the KAP values for hospital 1 and 3 were considerably lower.

A regression line was drawn to correlate skin dose with KAP. There was linear correlation for AP Pelvis (R=0.9913) projections combined (refer to table 4.3 and figure 4.5). Similarly a linear correlation was observed for AP pelvis projections at hospitals 1, 2 and 3 respectively (refer to appendices 20-22, and 51-53).

Table 4.3: KAP, skin and effective doses for Pelvis projections

	Hospital 1	Hospital 2	Hospital 3	Combined

*Median values

[#] Values are for linear fit unless otherwise stated.

Figure 4.5 Linear fit for AP Pelvis projections comparing skin dose and KAP values at the three research sites.

4.4 Skull projections

Table 4.4 shows the mean, median and 75th percentile KAP values, skin and effective doses for the PA and lateral skull projections at each hospital separately and then the combined values for PA and skull projections (refer to appendices 23-28).

The 75th KAP value for PA skull projections was 70.9 cGy.cm², 103.7 cGy.cm², and 77.1 cGy.cm² at hospitals 1, 2 and 3 respectively (refer to appendices 23-28). The combined 75th percentile of KAP was 86.7 cGy.cm². The median effective dose calculated by the PCXMC 2.0 programme was 0.0156 mSv, 0.0271 mSv, and 0.0223 mSv respectively, with a combined effective dose of 0.0197 mSv. The 75th percentile KAP value for hospital 2 was considerably higher than the combined KAP value, while the KAP values for hospital 1 and 3 were considerably lower.

For the LAT skull projections, the 75th KAP value was 62.8 cGy.cm², 80.4 cGy.cm², and 47.6 cGy.cm² at hospitals 1, 2 and 3 respectively. The combined 75th percentile of KAP was 62.3 cGy.cm². The median effective dose calculated by the PCXMC 2.0 programme was 0.0204 mSv, 0.0220 mSv, and 0.0155 mSv respectively, with a combined effective dose of 0.0178 mSv. The 75th percentile KAP value for hospital 2 was considerably higher than the combined KAP value, while the KAP values for hospital 1 and 3 were considerably lower.

A regression line was drawn to correlate skin dose with KAP. There was a linear correlation for both PA (R=0.8454) and LAT (R=0.7949) skull projections combined. Refer to (table 4.4 and figure 4.7 and 4.8). Similarly a strong linear correlation was observed for both PA and LAT Lumbar skull projections at hospitals 1, 2 and 3 respectively (refer to appendices 23-28 and 54-59).

Table 4.4: KAP, skin and effective doses for Skull projections

Figure 4.6 Linear fit for PA skull projections comparing skin dose and KAP values at the three research sites.

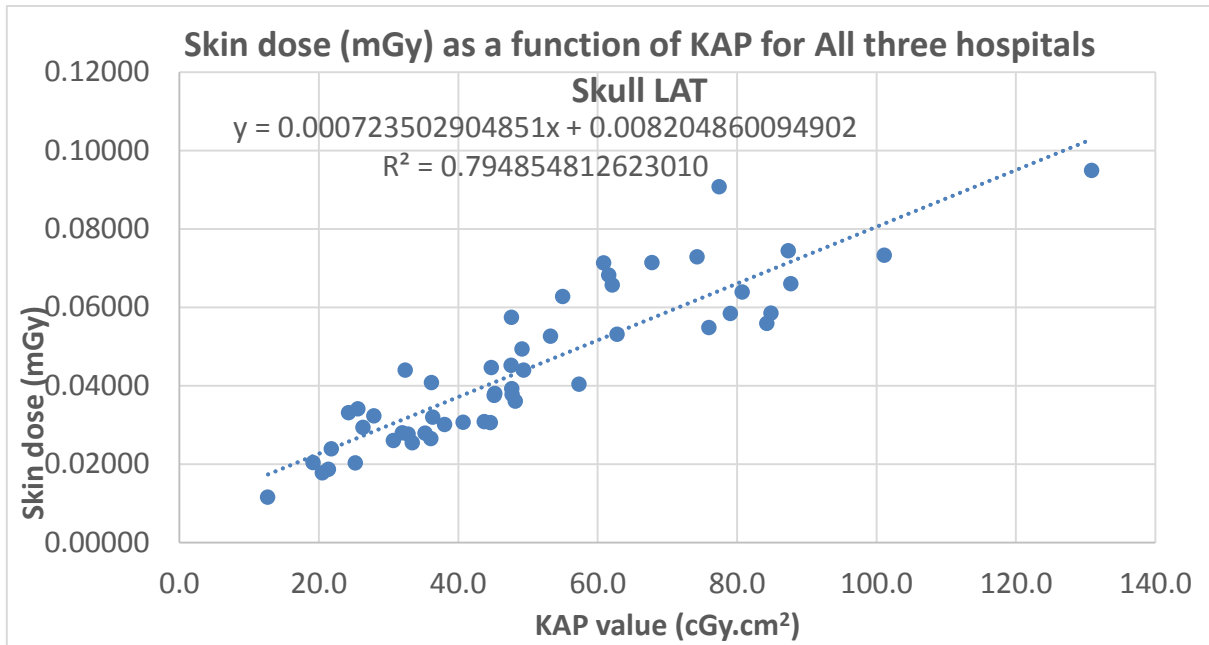

Figure 4.7 Linear fit for LAT Skull projections comparing skin dose and KAP values at the three research sites.

In this study the exposure factors and equipment parameters were entered into the PCXMC 2.0 software programme and entrance and effective doses were calculated. The 75th percentile KAP values were used to calculate conversion coefficients for the different radiographic examinations. The conversion coefficients for effective dose (E) were calculated with the following formulae (E/KAP) and skin dose (ESD/KAP) (Hansson & Karambatsakidou, 2000; Compagnone et al, 2005).

(Refer to table 4.5 below)

The results of the study were presented in this Chapter. The 75th percentile of KAP values were used to establish local DRLs and develop conversion coefficients for the conventional radiography examinations. The next chapter will discuss the results and make recommendations surrounding the research study.

CHAPTER 5: DISCUSSION

This study developed LDRL's for ESD and E from measured KAP values for four conventional x-ray examinations (AP and LAT chest, AP and LAT lumbar spine, AP pelvis, and PA and LAT skull) in three hospitals in Windhoek Namibia. Additionally conversion factors were derived from 3rd quartile values in order to have a simple indicator of patient dose in clinical practice. This chapter discusses our findings in relationship to similar studies in literature, and makes recommendations for future research.

5.1 Diagnostic reference levels (DRLs)

It is recommended that 3rd quartile of KAP measurements be used to establish DRLs (Edmonds, 2009; Seeram & Brennan, 2017).

5.1.1 LDRL's for Chest radiography

The LDRL's for Chest examinations in this study are presented in table 5.1. (combined values).

Table 5.1 Local DRLs for chest projections

	75 th percentile KAP (cGy.cm ²)	75 th percentile ESD (mGy)	75 th percentile E (mSv)
This study: PA chest	26.3	0.0333	0.0545
IAEA (1996)	NR	0.4	NR
Ng et al., (1998)	NR	0.3 (median)	NR
Osibote & de Azevedo (2008)	NR	0.24	NR
Sonowane et al., (2010)	NR	0.68	NR
Nyati et al., (2009)	NR	0.10	NR
Ofori et al., (2014)	NR	0.27 (median)	0.02
Aliasgharzadeh et al., (2015)	NR	0.37(mean)	0.04

Ofori et al, (2014)	NR	0.43 (median)	0.01
Aliasgharzadeh et al., (2015)	NR	0.99 (mean)	0.10
NR-not reported			

In this study, the local DRLs value for PA and LAT chest was 0.0333 mSv and 0.0663 mSv respectively by combining the skin dose measurements from the three research sites (refer to table 5.1). The ESDs for PA chest in hospital 2 and 3 were below the third quartile value but in hospital 1 was found to be higher (refer to table 4.1). The reason for the high ESD in hospital 1 could be attributed to the high mAs used at hospital 1 when compared to hospital 2 and 3. It is known that higher mAs with lower kVp will result in higher radiation dose to patients (Seeram & Brennan, 2017).

5.1.2 Lumbar spine radiography

The LDRL's for lumbar spine examinations in this study are presented in table 5.2. (combined values).

Table 5.2 Local DRLs for lumbar spine projections

	75 th percentile KAP (cGy.cm ²)	75 th percentile ESD (mGy)	75 th percentile E (mSv)
This study: AP lumbar spine	175.2	0.1970	0.3792
IAEA (1996)	NR	10	NR
Ng et al., (1998)	NR	9.1 (median)	NR
Osibote & de Azevedo (2008)	NR	2.60	NR
Sonowane et al., (2010)	NR	8.39	NR
Nyati et al., (2009)	NR	5.30	NR
Ofori et al, (2014)	NR	3.25 (median)	0.02
Aliasgharzadeh et al., (2015)	NR	2.18 (mean)	0.04
This study Lat lumbar spine	235.5	0.2740	0.2970

Ng et al., (1998)	NR	14 (median)	NR
Osibote & de Azevedo (2008)	NR	4.75	NR

Sonowane et al., (2010)	NR	15.66	NR
Nyati et al., (2009)	NR	NR	NR
Ofori et al, (2014)	NR	NR (median)	0.01
Aliasgharzadeh et al., (2015)	NR	5.36 (mean)	0.10
NR-not reported			

In this study, the local DRLs value for AP and LAT lumbar spine was 0.1970 mSv and 0.2740 mSv respectively by combining the skin dose measurements from the three research sites (refer to table 5.2). The ESDs for AP lumbar spine in hospital 1 and 3 were below the third quartile value but in hospital 2 was found to be higher (refer table 4.2). The reason for the high ESD in hospital 2 could be attributed to the high mAs used at hospital 2 when compared to hospital 1 and 3 (Seeram & Brennan, 2017).

5.1.3 Pelvis

The LDRL's for pelvis examinations in this study are presented in table 5.3. (combined values).

Table 5.3 Local DRLs for pelvis projections

	75 th percentile KAP (cGy.cm ²)	75 th percentile ESD (mGy)	75 th percentile E (mSv)
This study: AP pelvis	209.5	0.2497	0.3061
IAEA (1996)	NR	10	NR
Ng et al., (1998)	NR	5.3 (median)	NR
Osibote & de Azevedo (2008)	NR	NR	NR
Sonowane et al., (2010)	NR	8.03	NR
Nyati et al., (2009)	NR	2.98	NR
Ofori et al, (2014)	NR	1.31 (median)	NR
Aliasgharzadeh et al., (2015)	NR	1.76 (mean)	0.13
NR-not reported			

In this study, the local DRLs value for AP Pelvis was 0.2497 mSv by combining the skin dose measurements from the three research sites (refer to table 5.3). The ESDs for AP Pelvis in hospital 1 and 3 were below the third quartile value but in hospital 2 was found to be higher (refer to table 4.3). The reason for the high ESD in hospital 2 could be attributed to the high mAs used at hospital 2 when compared to hospital 1 and 3 (Seeram & Brennan, 2017).

5.1.4 Skull

The LDRL's for skull examinations in this study are presented in table 5.4. (combined values).

Table 5.4 Local DRLs for skull projections

	75 th percentile KAP (cGy.cm ²)	75 th percentile ESD (mGy)	75 th percentile E (mSv)
This study: PA skull	86.7	0.922	0.0267
IAEA (1996)	NR	5	NR
Ng et al., (1998)	NR	4.7 (median)	NR

Ofori et al., (2014)	NR	NR (median)	NR
Aliasgharzadeh et al., (2015)	NR	1.39 (mean)	0.01
This study Lat skull	62.3	0.584	0.0283
IAEA (1996)	NR	3	NR
Ng et al., (1998)	NR	3 (median)	NR
Osibote & de Azevedo (2008)	NR	NR	NR
Sonowane et al., (2010)	NR	5.86	NR
Nyati et al., (2009)	NR	NR	NR
Ofori et al., (2014)	NR	NR (median)	NR
Aliasgharzadeh et al., (2015)	NR	1.01 (mean)	0.01
NR-not reported			

In this study, the local DRLs value for AP and LAT skull was 0.0922mSv and 0.0584 respectively by combining the skin dose measurements from the three research sites (refer to table 5.4). The ESDs for PA and LAT lumbar spine in hospital 1 and 3 were below the third quartile value but in hospital 2 was found to be higher (refer to table 4.2). The reason for the high ESD in hospital 2 could be attributed to the high mAs used at hospital 2 when compared to hospital 1 and 3.

A comparison was done between hospital 1 and 3 because they both had equipment from the same manufacturer. Entrance skin doses were higher in hospital 1 than in hospital 3. This could be attributed to the fact that hospital 3 employed direct digital radiographic systems with automatic exposure control devices while hospital 1 employed computed radiography systems with manual exposures (Nyati et al, 2009; Seeram & Brennan, 2017).

5.1.5 Comparison of local DRLs with international values

The ESD's in this study was lower than those reported in the literature (IAEA, 1996; Ng et al., 1998; Osibote & Azevedo, 2008; Nyathi et al., 2009; Sonowane et al., 2009; Ofori et al., 2014; Aliasgharzadeh et al., 2015) refer to tables (5.1 to 5.4). In this study the lateral chest, lateral lumbar spine and lateral skull had higher skin doses when compared to the AP or PA projections of the same examination. This could be attributed to the shorter focus to skin distance for lateral examinations when compared to PA or AP examinations (Olowookere et al., 2011; Joyce et al, 2013).

5.2 Effective doses

In radiation protection effective dose is used to calculate annual dose limits to members of the public as well as radiation workers. It is used to maintain standards (Fisher & Fahey, 2017). In this study the highest effective dose recorded was for AP lumbar spine (0.3792 mSv) and the lowest (0.0267 mSv) for PA skull (refer to tables 5.2 and 5.4) respectively. The high dose reported for lumbar spine examinations is consistent with the literature (Khoo et al., 2003; IAEA, 2009). It can be noted from this study that the effective doses for (PA and LAT chest, AP and LAT lumbar spine, AP pelvis, and PA and LAT skull) are similar than those reported in the literature (refer to tables 5.1 to 5.4). The high effective doses in this study could be as a result of the adjustment of some of the tissue weighing factors (Obed et al., 2015).

5.3 Conversion Factors

The conversion factors established in this study can be used as a simple means to calculate entrance skin and effective doses from KAP values, thereby creating awareness amongst

radiology staff in the department. This can be achieved by multiplying the conversion factor with the displayed KAP value as indicated on table 4.5 in chapter 4.

5.4 Limitations of the study

- Possible limitations of the study was that the total field size (collimation) may not have been a true indication of the area exposed to radiation as some field sizes was not recorded. This may have affected the KAP values.

5.5 Conclusion and recommendations

The 75th percentile ESD's for (PA and LAT chest, AP and LAT lumbar spine, AP pelvis, and PA and LAT skull) in this study were lower than those reported in the literature, while the effective doses generally compared well with those reported in the literature.

The following are recommendations from the study:

It was noticed in this study that radiographers use manual exposures even though AEC devices were available. Therefore it is recommended that radiographers should undergo training on how to effectively use AEC devices during radiological examinations so that lower exposure factors can be achieved.

A national dose management programme should be established to create awareness of radiation doses amongst radiographers.

Radiographers in the clinical area should use the conversion coefficients (ESD/KAP) to convert KAP to ESD to get an immediate indication of patient doses. Similarly departmental managers and radiation safety officers (RSOs) should use the conversion coefficients (E/KAP) to calculate effective doses for the different radiographic projections.

The results of the study will be forwarded to the NRPA to be endorsed as initial local DRLs for Windhoek, Namibia.

It is further recommended that the study be repeated at five (5) year intervals in order to comply with Namibian legislation and as a means towards implementation of national diagnostic reference levels.

**Re: Strengthening Radiological Protection of Patients and Protection
in Medical Exposure RAF/9/033**

As you are aware, Namibia is one of the Member states in the African region which participates in projects under the International Atomic Energy Agency (IAEA). The above-mentioned project is one such project.

During a meeting held earlier this year in Libya, each member state was requested to participate in a pilot study under IAEA on the above – mentioned topic.

The purpose of the study is to strengthen radiological protection of patients and control medical exposure. On the other hand, we hope to improve diagnostic information content on images produced, reduce unnecessary radiation exposure, reduce medical costs and improve departmental management.

In order to achieve this, surveys of image quality and patient doses in simple radiographic examinations will be done, guidance levels established and compared with international standards.

There is a need for this study to be done in a practical set-up. Therefore Windhoek Central Hospital and Katutura State Hospital were identified for this project.

The project is divided into two phases. The first phase of the project is expected to be finalised towards the end of October 2005 and the second phase will start in 2006.

The following staff members from your departments will be key role players in the study.

1. Ms L. Beukes (Control Radiographer): National Coordinator
2. Ms N. Bloodstaaan (Radiographer): Project Coordinator
3. Ms. N. Cupido (Chief Radiog.: Training): Assist Project Coordinator
4. Dr. J. A. Gabone (Radiologist): Consultant
5. Ms. Sikai Shambira (Medical Physicist): Consultant

I therefore request you kindly to support this project and assist the staff members to carry out these activities successfully.

Thanking you in anticipation.

APPENDIX 2:

Letter of permission: Permanent Secretary

P O Box 20323

Windhoek

Namibia

29 May 2013

**To: The Permanent Secretary
Ministry of Health and Social Services
Private Bag 13301
Windhoek**

Dear Sir/Madam

RE: Request for permission to carry out a research study at Windhoek Central and Katutura Intermediate hospitals.

I am registered for a Masters Degree in Technology - Radiography (Diagnostic), at the Cape Peninsula University of Technology, (student number 213009641).

As a course requirement I am expected to complete a research project. The title of the study is **“Measurement of radiation doses to patients undergoing routine x-ray examinations in Windhoek Namibia to develop diagnostic reference levels”**.

As part of a global effort to minimise radiation doses delivered to patients radiographers are obliged to keep radiation doses as low as reasonably achievable. The study intends to measure radiation doses delivered to patients during routine x-ray examinations. A portable Dose Area Product (DAP) meter will be attached to the x-ray tube housing of the collimator and will be used to measure the radiation doses delivered to some patients. The study will involve patients referred for the Chest, Lumbar Spine, Pelvis and Skull radiographs. Participants will be asked to participate voluntarily after the research objectives have been explained to them thoroughly. After consenting to the study, the patients' weight, height, age,

gender and thickness of anatomical part under investigation will be recorded along with the exposure factors used during the examination. Besides these measurements there will be no difference to what is routinely done in the department and there will be no interference with the management of patients as well as the daily duties of radiographers employed at these hospitals.

I have selected the departments at Windhoek Central Hospital (WCH) and Katutura Intermediate Hospital (KIH) to conduct my research as it is the largest public hospitals and utilise computed radiography techniques which may be associated with higher radiation doses. It is anticipated that the research may contribute towards the optimisation of radiation doses delivered to patients.

In addition I am also an employee at the University of Namibia (Assistant Lecturer) responsible for Clinical Practice at Windhoek Central Hospital and Katutura Intermediate Hospital respectively; on staff development leave to pursue this qualification. I am therefore familiar with the radiography department and management of radiographic matters.

The data obtained in this study will be strictly confidential. In order to respect the patient's right to privacy, all measurements will be taken inside the x-ray room. Patients will be included in the study on a voluntary basis after careful explanation of the research and after informed consent has been obtained. Consent letters will be in English and will be translated into indigenous languages by means of a translator. The data obtained will be stored and locked in the researcher's office, where only the researcher has access. The data collection form will be coded in order to protect the identity of the research participants and maintain anonymity. The data recorded from the patient will be limited to the patients' weight, height, and anatomical thickness, age, gender and exposure factors (Appendix 13). Please see the attached patient information leaflet and consent form (Appendix 12).

It is anticipated that the proposed study will have the following advancement in knowledge and benefits:

- Development of preliminary diagnostic reference levels values for chest posterior-anterior (PA) and lateral (LAT) lumbar spine anterior-posterior (AP) and LAT pelvis AP and skull PA and LAT which may aid in the optimisation of radiographic technique.
- The insight from this study may create awareness of radiation doses and provide knowledge about diagnostic reference levels amongst radiographers in Windhoek, Namibia.
- The results will contribute to research knowledge about radiation doses in Windhoek.
- The diagnostic reference levels can be used as a benchmark to support the need for legislative measures to implement diagnostic reference levels at national level.

- The data obtained may inform whether radiographic practices in Windhoek conform or differ to that of international norms.

The proposed study will have no financial implication for your Ministry and no consumables of the hospital will be used.

I hereby request your support in granting me permission to carry out this proposed study at the above mentioned hospitals. Please find attached a copy of my full proposal and data collection instruments for further reference. Should you have any enquiries regarding this research do not hesitate to contact me or my supervisors.

I trust that my request will receive your approval.

Yours faithfully

Edwin Ralph Daniels

REF 158 00 05

Technical data

All technical data are valid for the specified ambient conditions according to IEC 60580.

Ionization chamber

Response	
without absorber	800 pC / $\mu\text{Gy}\cdot\text{m}^2$
with absorber (0.5 mm Al)	920 pC / $\mu\text{Gy}\cdot\text{m}^2$
Leakage current	$\leq 0.1 \text{ pA}$
Response versus radiation quality	- 6% / + 0% (50 kV ... 150 kV, acc. to IEC 60580)
Quality equivalent filtration (70 kV)	0.2 mm Al
Transparency	> 70%
Useful field	(1 ... 200) cm^2
Chamber voltage	300 V
Distance of the electrodes	6 mm
Stabilization time	5 min

Measuring device

Combined standard uncertainty (acc. to IEC 60580) $\pm 25 \%$

Measured quantity	Dose area product		Dose area product rate	
	High Resolution	High Rate	High Resolution	High Rate
Mode				
Unit of measure	$[\mu\text{Gy}\cdot\text{m}^2]$	$[\mu\text{Gy}\cdot\text{m}^2]$	$[\mu\text{Gy}\cdot\text{m}^2/\text{min}]$	$[\mu\text{Gy}\cdot\text{m}^2/\text{min}]$
Digital resolution	0.01	0.1	0.6	6
Measuring range	0.1 ... 99 999 999	1 ... 99 999 999	6.0 ... 280 000	60 ... 2 200 000

Rated range of use

Radiation quality	(40 ... 150) kV
Dose area product rate (High Res. Mode)	$(0.6 \dots 2.8 \cdot 10^5) \mu\text{Gy}\cdot\text{m}^2/\text{min}$
Dose area product rate (High Rate Mode)	$(6.0 \dots 2.2 \cdot 10^6) \mu\text{Gy}\cdot\text{m}^2/\text{min}$
Air kerma rate	$(6.0 \dots 1.1 \cdot 10^5) \text{mGy}/\text{min}$ (at the position of the chamber)
Air pressure	(80.0 ... 106.0) kPa
Temperature	(+10 ... +40) °C
Air humidity	(10 ... 80) % rel. humidity (max. 20 g/m ³)

The maximum dose area product rate must not be exceeded.
 The ionization chamber must frame the radiation field at all times!

Serial interface	RS-485; half-duplex
Supply voltage (+U _S)	(+ 10 ... + 30) V DC
with Battery for VacuDAP (REF) 950 00 64)	(+ 6.5 ... + 8.4) V DC
Power consumption	max. 3 W
Weight without guide rails	260 g

Only values given with tolerance ranges, or limits are guaranteed. All other values are for information only. Subject to change.

3 October 2013
CPUT/HW-REC 2013/H32

Faculty of Health and Wellness Sciences – Nursing and Radiography Department

Dear Mr Edwin Ralph Daniels

APPLICATION TO THE HW-REC FOR ETHICAL CLEARANCE

Approval was granted on 20 September 2013 by the Health and Wellness Sciences-REC to Edwin Ralph Daniels for your Ethical Clearance application. This approval is for research activities related to an MTech: Radiography at this Institution.

Title: Measurement of radiation doses to patients undergoing routine x-ray examinations in Windhoek, Namibia to develop diagnostic reference levels.

INTERNAL SUPERVISOR: Mrs F Davidson

INTERNAL CO-SUPERVISOR: Mr A Speelman

Comment:

Approval will not extend beyond 3 October 2014. An extension should be applied for 6 weeks before this expiry date should data collection and use/analysis of data, information and/or samples for this study continue beyond this date.

Note:

The investigator(s) should understand the conditions under which they are authorized to carry out this study and they should be compliant to these conditions. **It is required that the investigator(s) complete an annual progress report that should be submitted to the HW-REC in December of that particular year, for the HW-REC to be kept informed of the progress and of any problems you may encounter.**

Attachments: Research application form[1].doc (43 KB)

Dear Mr. Daniels

Please submit your request letter with all the relevant documents attached to the Permanent Secretary's office. The following documents should be attached;

- request/cover letter addressed to the PS,
- full research proposal with all the data collection tools attached,
- IRB approval from your university
- completed research application form with you cv attached

You are advised to submit the hard copies. For further communication, please make use my work email: eshaama@mhss.gov.na. Attached is the research application form that you have to complete.

Regards,
Ester

TO EHO IT MAU CONCERN

RE: Request for permission to carry out a research study at Windhoek Central and Katutura Intermediate hospitals.

I am a postgraduate student (Masters in Technology- Radiography (diagnostic), registered at the Cape Peninsula University of Technology, registration number 213009641), In addition I am also an employee at the University of Namibia (Assistant Lecturer) responsible for Clinical Practice at Windhoek Central Hospital and Katutura Intermediate Hospital respectively; on staff development leave to peruse this qualification.

It is a requirement at this level for a student to conduct research for fulfilment of the award of a Masters degree.

The title of the study is "Measurement of radiation doses to patients undergoing routine x-ray examinations in Windhoek Namibia to develop diagnostic reference levels".

I have selected the departments at Windhoek Central Hospital (WCH) and Katutura Intermediate Hospital (KIH) to conduct my research as it is the largest public hospitals and utilise computed radiography techniques which may be associated with higher radiation doses. It is anticipated that the research may contribute towards the optimisation of radiation doses delivered to patients.

I hereby request the support in my studies and permission to carry out this proposed study and the above mentioned hospitals.

A copy of the summarised proposal is attached and full proposal availed on request.

Subject: RE: PERMISSION TO CONDUCT RESEARCH

Dear Edwin

We are guided by the Act and it's Regulations and therefore I would like to quote some of the applicable provisions for your information

Reg 34(4): '..the exposure of humans for medical research must be conducted subject to conditions imposed by the Authority if such research is justified..'

Reg 37: '..the optimisation of protection of persons exposed for medical research purposes, if such medical exposure does not produce direct benefit to the exposed persons, must be subjected to individual dose constraints..'

Now in reference to the above I take it that the data that you will collect come from the routine exposure of patients. In other words the exposure is not for research purpose, but for the direct benefit of the patient. So you are only using the data that result from the justified exposure. On this basis I would submit that the approval from the Ministry's research committee may be sufficient.

However I would very much encourage you to work with Vera and for that the central subject matters is referenced under Regulation 38.

Dear Mr Daniels

RE: ACCESS TO MEDICAL IMAGING FOR RESEARCH PAPER

The Partners recognize receipt of your emailed request to use Medical Imaging for your research in fulfillment of the requirements for your M Tech (Radiology) as received on 31 May 2013.

It is noted that the research is an endeavor to develop diagnostic reference levels for patients undergoing routine x-ray examinations that may contribute to optimization of radiation doses delivered to patients and that you wish to gain access to the clinics located at Mediclinic, Roman Catholic Hospital and Rhino Park for the purpose of data gathering.

It is further noted that data gathered from the three sites will be kept strictly confidential.

Referring to the above, the partners are pleased to inform you that your request has been approved and wish you success with the dissertation.

From an operational perspective, you are requested to provide details of when you will be at the various clinics, what information you will be seeking/ the Practice will need to make available and the methodology you will use to collect data. You are also politely requested to report to both the Radiologist/s on duty and the Clinic Manager when entering and leaving the clinic.

Partners look forward to an ongoing academic partnership with you and your department.

Yours sincerely

APPENDIX 38: PATIENT INFORMATION LEAFLET AND CONSENT FORM

PARTICIPANT INFORMATION LEAFLET AND CONSENT FORM

TITLE OF THE RESEARCH PROJECT: Measurement of radiation doses to patients undergoing routine x-ray examinations in Windhoek Namibia to develop diagnostic reference levels.

PRINCIPAL INVESTIGATOR: Edwin Ralph Daniels.
Registered for: M Tech Radiography at the Cape
Peninsula University of Technology.

ADDRESS: P.O.Box 20323, Windhoek, Namibia.

Contact number: +27 0721374566 or + 00264 812575787

Dear Participant,

As a radiographer it is part of our goal to continuously improve the quality of our services as well as striving into research ventures that will bring new knowledge, enabling us to improve our patient management service.

On this note we request your participation in a project titled: **“Measurement of radiation doses to patients undergoing routine x-ray examinations in Windhoek Namibia to develop diagnostic reference levels.”**

Please take some time to read the information presented here which will explain the details of this project. Please ask the principal investigator about any part of the project that you do not fully understand. It is very important that you are fully satisfied as to what the research entails. Your participation is **entirely voluntary** and you are free to withdraw at any stage if you say no, this will not affect you negatively in any way whatsoever.

The research study has been approved by the Permanent Secretary (Ministry of Health and Social Services as well as the Cape Peninsula University of Technology research Ethics committee of the Faculty of Health and Wellness Sciences. The study has also been approved by the heads of the various radiology departments and is supported by the National Radiation Protection Authority of Namibia.

Purpose of research study:

The study aims to measure radiation to patients undergoing routine x-ray examinations in Windhoek Namibia and develop diagnostic reference levels.

What is the study about?

The study will explore whether radiographers optimise the radiation delivered to patients during four selected radiography procedures, namely chest, skull, lumbar spine and pelvis. These examinations have been selected because they are frequently performed in these hospitals.

In a global effort to minimise the harmful effects of ionising radiation and an effort to keep radiation doses as low as reasonably achievable (ALARA) the researcher decided to measure radiation doses that patients receive during the above mentioned procedures and establish diagnostic reference levels for these procedures. The diagnostic reference levels will be compared with international reference levels and determine whether our radiation protection measures conform to international levels or not.

The results will also be forwarded to the National Radiation Protection Authority of Namibia and propose that these values be used as provisional diagnostic reference levels until such a time when National reference values are established. Once these reference values have been established x-ray departments can compare their radiation practices against these values and investigate the cause of the dose variation if the values are exceeded.

Why have you been invited to participate?

You have been chosen to participate because the Doctor have referred you for one of the x-ray procedures we are interested in monitoring.

What will your responsibilities be?

To allow us to measure your weight, height, and anatomical thickness for the body part under examination. You will be asked to stand on a digital scale and your weight will be recorded. You will also stand against the wall of the x-ray room and your height will be measured. The radiographer will then position you as per departmental protocol and measure the distance from the x-ray source to your skin. This measurement will be used to determine the thickness of your body part in the centre of the x-ray source. The radiographer will then record the dose area

product displayed on the DAP meter after exposure. This is normally not part of an x-ray procedure.

Will you benefit from this research?

There are no direct benefits to you as a volunteer. There will be no results that can tell us anything about your health or possible diseases. Your radiographs will be reported by radiologist as per normal routine. This study will not interfere with your results or management of your health. However the study will help us determine whether we are conforming to international norm and whether or not our radiation protection practices are optimised.

Are there any risks from taking part in this research?

X-rays usually involve radiation which poses a small risk. The risk of this study is however negligible. We will only perform the normal radiographic views that the Doctor requested without any alteration in the positioning technique procedure, or reading of the image.

If you do not agree what alternatives do you have?

Whether or not you participate in this study will not affect your clinical care in any way.

Who will have access to the data?

All information collected will be treated as confidential. In order to assure anonymity and protect your identity you will be assigned a study code. Access to the information will only be limited to the principal investigator and immediate supervisors. There will be no means to trace the data to the participant as the study will only record data related to radiation exposure received during the x-ray examination procedure.

Data to be collected

The following data will be collected from each participant:

- Age
- Gender (male/female)
- Weight

- Height
- Thickness of anatomical part under examination

No other data will be collected.

Will you be paid to take part in this study?

You will not be paid to take part in this study, and you will not incur any cost either.

(Declaration by participant, Principal investigator and Translator.)

NB...!

(Consent form must be signed by Participant, Principal Researcher & Language Translator)

Declaration by participant:

By signing below, I.....agree to take part in a research study titled: Measurement of radiation doses to patients undergoing routine x-ray examinations in Windhoek Namibia to develop diagnostic reference levels.

I declare that:

- I have read or had read to me this information and consent form and it is written in a language with which I am fluent and comfortable. I have had a chance to ask questions and all my questions have been adequately answered.
- I understand that taking part in this study is voluntary and I have not been pressurized to take part.
- I understand that all data collected in this research will be handled confidentially.
